About this document

This publication provides application programmers with complete information about enabling applications for multicultural support for the AIX® operating system. It also provides system administrators with complete information about enabling networked environments for using globalization features in the AIX operating system. Programmers and system administrators can use this publication to gain knowledge of globalization guidelines and principles. Topics include locales, code sets, input methods, subroutines, converters, character mapping, culture-specific information, and the message facility.

Highlighting

The following highlighting conventions are used in this publication:

Bold	Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system. Also identifies graphical objects such as buttons, labels, and icons that the user selects.
<i>Italics</i>	Identifies parameters whose actual names or values are to be supplied by the user.
Monospace	Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or information you should actually type.

Case-sensitivity in AIX

Everything in the AIX operating system is case-sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the **ls** command to list files. If you type **LS**, the system responds that the command is not found. Likewise, **FILEA**, **FiLea**, and **filea** are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

ISO 9000

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

AIX globalization

Globalization provides commands and Standard C Library subroutines for a single worldwide system base. An globalized system has no built-in assumptions or dependencies on language-specific or cultural-specific conventions such as:

- Code sets
- Character classifications
- Character comparison rules
- Character collation order
- Numeric and monetary formatting
- Date and time formatting
- Message-text language

All information pertaining to cultural conventions and language is obtained at process run time.

The following capabilities are provided by the globalization features to maintain a system running in an international environment:

- “Separation of messages from programs”
- “Conversion between code sets” on page 2

What's new in AIX globalization

Read about new or significantly changed information for the AIX globalization topic collection.

March 2013

The following information is a summary of the updates made to this topic collection:

- Updated information about the Unicode character set in “Conversion between code sets” on page 2.

November 2012

The following information is a summary of the updates made to this topic collection:

- Added Unicode Common Locale Data Repository (CLDR) definitions and support in “Supported languages and locales” on page 167.
- Added four new server-side locales to the **Unicode encoded languages and locales in AIX** table in “Supported languages and locales” on page 167: Bengali (Bangladesh), Khmer (Cambodia), Uzbek (Uzbekistan - Cyrillic, Latin, and Arabic script), and Uzbek (Uzbekistan - Latin script).

How to see what's new or changed

In this PDF file, you might see revision bars (|) in the left margin that identify new and changed information.

Separation of messages from programs

It is necessary to keep messages separate from the programs and provide them in the form of message catalogs that a program can access at run time. It facilitates translations of messages into various languages and to make the translated messages available to the program based on a user's locale.

Related concepts:

“Message facility” on page 148

It is necessary to keep messages separate from the program by providing them in the form of message catalogs that the program can access at run time. This arrangement facilitates translations of messages into various languages and make them available to a program based on a user's locale. To aid in this task, commands and subroutines are provided by the Message Facility.

Conversion between code sets

A character is any symbol that is used for the organization, control, or representation of data. A group of such symbols that are used to describe a particular language make up a character set. A code set contains the encoding values for a character set. The encoding values in a code set provide an interface between the system and its input and output devices. Multicultural support supplies converters that conform to character-encoding values that are found in different code sets.

Historically, the effort was directed at encoding the English alphabet. It was sufficient to use a 7-bit encoding method for this purpose because the number of English characters is not large. To support larger alphabets, such as the Asian languages, such as Chinese, Japanese, and Korean, additional code sets were developed that contained multibyte encoding. Now, Unicode, a character set for supporting the worldwide information processing, is used as the basic interchange format in the operating system level. The UTF-8, UTF-16, and UTF-32 code sets are the major Unicode encoding schemes for system applications.

A globalized program must accurately read data that are generated in different code set environments and process the information accurately. Knowing the current code set can aid in code set conversion. You can use the `nl_langinfo(CODESET)` subroutine to obtain the current code set in a process. The return value is a char pointer that is the name of the code set in the system.

Related concepts:

“Converters overview for programming” on page 81

Multicultural support provides a base for globalization in which data often can be changed from one code set to another. Support of several standard converters for this purpose is provided.

Input method support

The input of characters becomes complicated for languages having large character sets. For example, in Chinese, Korean, and Japanese, where the number of characters is large, it is not possible to provide one-to-one key mapping for a keystroke to a character. However, a special input method enables the user to enter phonetic or stroke characters and have them converted into native-language characters.

A keyboard map associated with each keyboard matches sequences of one or more keystrokes with the appropriate character encoding.

Related concepts:

“Input methods” on page 119

For an application to run in the international environment for which globalization provides a base, input methods are needed. The Input Method is an application programming interface (API) that allows you to develop applications independent of a particular language, keyboard, or code set.

Converters overview

Globalization provides a base for globalization to allow data to be changed from one code set to another. You might need to convert text files or message catalogs. There are several standard converters for this purpose.

When a program sends data to another program residing on a remote host, the data can require conversion from the code set of the source machine to that of the receiver. For example, when communicating with an IBM[®] VM system, the system converts its ISO8859-1 data to EBCDIC. Code sets

define character and control function assignments to code points. These coded characters must be converted when a program receives data in one code set but displays it in another code set.

Related concepts:

“Converters overview for programming” on page 81

Multicultural support provides a base for globalization in which data often can be changed from one code set to another. Support of several standard converters for this purpose is provided.

Using the message facility

To facilitate the translation of messages into various languages and to make them available to a program based on a users locale, it is necessary to keep messages separate from the program and provide them in the form of message catalogs that a program can access at run time. To aid in this task, the Message Facility provides commands and subroutines. Message source files containing application messages are created by the programmer and converted to message catalogs. These catalogs are used by the application to retrieve and display messages, as needed. Message source files can be translated into other languages and converted to message catalogs without changing and recompiling a program.

The message facility includes the following commands for displaying messages with a shell script or from the command line:

Command	Description
dspcat	Displays all or part of a message catalog
dspmsg	Displays a selected message from a message catalog

These commands use the NLSPATH environment variable to locate the specified message catalog. The NLSPATH environment variable lists the directories containing message catalogs. These directories are searched in the order in which they are listed. For example:

```
NLSPATH=/usr/lib/nls/msg/%L/%N:/usr/lib/nls/msg/prime/%N
```

The %L and %N special variables are defined as follows:

Special Variable	Description
%L	Specifies the locale-specific directory containing message catalogs. The value of the LC_MESSAGES category or the LANG environment variable is used for the directory name. The LANG, LC_ALL, or LC_MESSAGES environment variable can be set by the user to the locale for message catalogs.
%N	Specifies the name of the catalog to be opened.

If the **dspcat** command cannot find the message, the default message is displayed. You must enclose the default message in single-quotation marks if the default message contains %n\$ format strings. If the **dspcat** command cannot find the message and you do not specify a default message, a system-generated error message is displayed.

The following example uses the **dspcat** command to display all messages in the existing msgerrs.cat message catalog:

```
/usr/lib/nls/msg/$LANG/msgerrs.cat:  
dspcat msgerrs.cat
```

The following output is displayed:

```
1:1 Cannot open message catalog %s  
Maximum number of catalogs already open  
1:2 File %s not executable  
2:1 Message %d, Set %d not found
```

By displaying the contents of the message catalog in this manner, you can find the message ID numbers assigned to the msgerrs message source file by the **mkcatdefs** command to replace the symbolic

identifiers. Symbolic identifiers are not readily usable as references for the **dspmsg** command, but using the **dspcat** command as shown can give you the necessary ID numbers.

The following is a simple shell script called **runtest** that shows how to use the **dspmsg** command:

```
if [ - x ./test ]
  ./test;
else
  dspmsg msgerrrs.cat -s 1 2 '%s NOT EXECUTABLE \n' "test";
  exit;
```

Note: If you do not use a full path name, as in the preceding examples, be careful to set the **NLSPATH** environment variable so that the **dspcat** command searches the correct directory for the catalog. The **LC_MESSAGES** category or the value of the **LANG** environment variable also affects the directory search path.

Setting multicultural support for devices

Multicultural support uses the locale setting to define its environment. The locale setting is dependent on the user requirements for data processing and language that determines input and output device requirements. The system administrator is responsible for configuring devices that are in agreement with user locales.

Terminals (tty devices)

Use the **setmaps** command to set the terminal and code-set map for a given tty or pty. The **setmaps** file format defines the text of the code-set map file and the terminal map file.

The text of a code-set map file is a description of the code set, including the type (single byte or multibyte), the memory and screen widths (for multibyte code-sets), and the optional converter modules to push on the stream. The code set map file is located in the **/usr/lib/nls/csmmap** directory and has the same name as the code set. For more information, see *Converter Modules in AIX Version 7.1 General Programming Concepts: Writing and Debugging Programs*.

Printers

Virtual printers inherit the default code set of incoming jobs from the **LANG** entry in the **/etc/environment** file. A printer subsystem can support several virtual printers. If more than one virtual printer is supported, each can have a different code set. The suggested printer subsystem scenarios areas follows:

- The first scenario involves several queues, several virtual printers, and one physical printer. Each virtual printer has its own code set. The print commands specify which queue to use. The queue in turn specifies the virtual printer with the appropriate code set. In this scenario, the user needs to know which queue is attached to which virtual printer and the code set that is associated with each.
- The second scenario is similar to the first, but each virtual printer is attached to a different printer.
- The third scenario involves using the **qpri** command to specify the code set. In this option, there are several queues available and one virtual printer. The virtual printer uses the inherited default code set.

Use the **qpri** command with the **-P-x** flags to specify the queue and code set. If the **-P** flag is not specified, the default queue is used. If the **-x** flag is not used, the default code set for the virtual printer is used.

Low-function terminals

Low-function terminals (LFTs) support single-byte code-set languages using key maps. An LFT key map translates a key stroke into a character string in the code set. A list of all available key maps is in the **/usr/lib/nls/loc** directory. LFT does not support languages that require multibyte code sets.

The default LFT keyboard setting and associated font setting are based on the language selected during installation. The possible default code sets are as follows:

- ISO8859-1
- ISO8859-2
- ISO8859-4
- ISO8859-5
- ISO8859-6
- ISO8859-7
- ISO8859-8
- ISO8859-9
- ISO8859-15

You can change the default settings in the following ways:

- To change the default font for next reboot, use the **chfont** command with the **-n** flag.
- To change the default keyboard for next reboot, use the **chkbd** command with the **-n** flag.

The **lsfont** and **lskbd** commands list all the fonts and keyboard maps that are currently available to the LFT.

The LFT font libraries for all the supported code sets are in the **/usr/lpp/fonts** directory.

Changing the language environment

A number of system operations are affected by the language environment. Some of these operations include collation, time of day and date representation, numeric representation, monetary representation, and message translation. The language environment is determined by the value of the **LANG** environment variable, and you can change that value with the **chlang** command. The **chlang** command can be run from the command line or from SMIT.

To use the SMIT fast path to change the language environment, type `smit chlang` on the command line.

Changing the default keyboard map

Multicultural support also enables you to specify the correct keyboard for the language you want to use. The operating system provides a number of keyboard maps for this purpose. You can change the default keyboard map for LFT terminals using Web-based System Manager (type **wsm**, then select **Devices**), the SMIT fast path, `smit chkbd`, or the **chkbd** command. The change does not go into effect until you restart the system.

Note: Do not assume any particular physical keyboard is in use. Use an input method based on the locale setting to handle keyboard input.

ICU4C libraries

Common Component ICU4C stands for International Components for Unicode for C/C++ class libraries. It provides globalization utilities for writing global applications in C/C++ programming languages. ICU4C libraries are being used by numerous products running on AIX operating system.

Locales

An globalized system has no built-in assumptions or dependencies on code set, character classification, character comparison rules, character collation order, monetary formatting, numeric punctuation, date and time formatting, or the text of messages. A *locale* is defined by these language and cultural conventions. An globalized system processes information correctly for different locations. For example, in the United States, the date format, 9/6/2002, is interpreted to mean the sixth day of the ninth month of

the year 2002. The United Kingdom interprets the same date format to mean the ninth day of the sixth month of the year 2002. The formatting of numeric and monetary data is also country-specific, for example, the U.S. dollar and the U.K. pound.

All locale information must be accessible to programs at run time so that data is processed and displayed correctly for your cultural conventions and language. This process is called localization. Localization consists of developing a database containing locale-specific rules for formatting data and an interface to obtain the rules.

Understanding locale

A locale comprises the language, territory, and code set combination used to identify a set of language conventions. These conventions include information on collation, case conversion, and character classification, the language of message catalogs, date-and-time representation, the monetary symbol, and numeric representation.

Locale information contained in the **locale definition** source files must first be converted into a locale database by the **localedef** command. The **setlocale** subroutine can then access this information and set locale information for applications. To deal with locale data in a logical manner, locale definition source files are divided into six categories. Each category contains a specific aspect of the locale data. The **LC_*** environment variables and the **LANG** environment variable can be used to specify the desired locale.

Related concepts:

“Understanding locale categories” on page 7

A *locale category* is a particular grouping of language-specific and cultural-convention-specific data. For instance, data referring to date-and-time formatting, the names of the days of the week, names of the months, and other time-specific information is grouped into the **LC_TIME** category. Each category uses a set of keywords that describe the particulars of that locale subset.

Typical user scenarios

Users might encounter several multicultural scenarios on the system. This section lists common scenarios with suggested actions to be taken.

- User keeps default code set

The user might be satisfied with the default code set for language-territory combinations even where more than one code set is supported. The user might keep the default code set if the current user environment uses that code set, or if the user is new and has no code set preference.

The language-territory selected at system installation time is defaulted to the appropriate locale based on the default code set. The default keyboard mappings, default font, and message catalogs are all established around the default code set. This scenario requires no special action from the user.

- User changes code set from the default code set

Users of a Latin-1 or Japanese locale might want to migrate their data and multicultural support environment to a different (nondefault) code set. This can be done in the following fashion:

- When the user has existing data that requires conversion

Flat text files that require conversion to the preferred code set can be converted through the Users application in Web-based System Manager, the SMIT Manage the Language Environment[®] menu, or the **iconv** utility. User-defined structured files require conversion through user-written conversion tools that use the **iconv** library functions to convert the desired text fields within the structured files.

- When the user wants to change to the other code set

Where more than one code set is supported for a language-territory combination, the user may change to a nondefault locale by using:

- The Users application in Web-based System Manager
- The SMIT Manage Language Environment menu
- The **chlang**, **chkbd**, and **chfont** commands.

Locale naming conventions

Each locale is named by its locale definition source file name. These files are named for the language, territory, and code set information they describe. The following format is used for naming a locale definition file:

```
language[_territory][.codeset][@modifier]
```

For example, the locale for the Danish language spoken in Denmark using the ISO8859-1 code set is `da_DK.ISO8859-1`. The `da` stands for the Danish language and the `DK` stands for Denmark. The short form of `da_DK` is sufficient to indicate this locale. The same language and territory using the ISO8859-15 code set is indicated by `da_DK.8859-15`.

System-defined locale definition files are provided to show the format of locale categories and their keywords. The `/usr/lib/nls/loc` directory contains the locale definition files for system-defined locales. The `C`, or `POSIX`, locale defines the ANSI C-defined standard locale inherited by all processes at startup time. To obtain a list of system-defined locale definition source files, enter the following on the command line:

```
/usr/lib/nls/lsmle -c
```

Installation default locale

The installation default locale refers to the locale selected at installation. For example, when prompted, a user can specify the French language as spoken in Canada during the installation process. The code set automatically defaults to the ISO8859-1 code set.

With this information, the system sets the value of the default locale, specified by the `LANG` environment variable, to `fr_CA` (`fr` for ISO8859-1 French and `CA` for Canada). Every process uses this locale unless the `LC_*` or `LANG` environment variables are modified. The default locale can be changed by using the Manage Language Environment menu in SMIT. For more information, see System management interface tool (SMIT) overview in *AIX Version 7.1 Operating system and device management*.

The C or POSIX locale

This locale refers to the ANSI C or POSIX-defined standard for the locale inherited by all processes at startup time. The `C` or `POSIX` locale assumes the 7-bit ASCII character set and defines information for the six previous categories.

Understanding locale categories

A *locale category* is a particular grouping of language-specific and cultural-convention-specific data. For instance, data referring to date-and-time formatting, the names of the days of the week, names of the months, and other time-specific information is grouped into the `LC_TIME` category. Each category uses a set of keywords that describe the particulars of that locale subset.

The following standard categories can be defined in a locale definition source file:

`LC_COLLATE`

Defines character-collation or string-collation information.

`LC_CTYPE`

Defines character classification, case conversion, and other character attributes.

`LC_MESSAGES`

Defines the format for affirmative and negative responses.

`LC_MONETARY`

Defines rules and symbols for formatting monetary numeric information.

`LC_NUMERIC`

Defines rules and symbols for formatting nonmonetary numeric information.

`LC_TIME`

Defines a list of rules and symbols for formatting time and date information.

Note: Locale categories can only be modified by editing the locale definition source file. Do not confuse them with the environment variables of the same name, which can be set from the command line.

Related concepts:

“Understanding locale” on page 6

A locale comprises the language, territory, and code set combination used to identify a set of language conventions. These conventions include information on collation, case conversion, and character classification, the language of message catalogs, date-and-time representation, the monetary symbol, and numeric representation.

Understanding locale environment variables

Multicultural support uses several environment variables to influence the selection of locales. You can set the values of these variables to change search paths for locale information:

LANG

Specifies the installation default locale.

Note: The **LANG** environment variable value is established at installation. (This is the locale every process uses unless the **LC_*** environment variables are set). The **LANG** environment variable can be changed by using the Manage Language Environment menu in SMIT. For more information about using SMIT, see Available system management interfaces in *AIX Version 7.1 Operating system and device management*. The C and POSIX locales are designed to offer the best performance.

LC_ALL

Overrides the value of the **LANG** environment variable and the values of any other **LC_*** environment variables.

LC_COLLATE

Specifies the locale to use for **LC_COLLATE** category information. The **LC_COLLATE** category determines character-collation or string-collation rules governing the behavior of ranges, equivalence classes, and multicharacter collating elements.

LC_CTYPE

Specifies the locale to use for **LC_CTYPE** category information. The **LC_CTYPE** category determines character handling rules governing the interpretation of sequences of bytes of text data characters (that is, single-byte versus multibyte characters), the classification of characters (for example, alpha, digit, and so on), and the behavior of character classes.

LC_FASTMSG

Specifies that default messages are used for the C and POSIX locales and that **NLSPATH** are ignored when **LC_FASTMSG** is set to true. Otherwise, POSIX compliant message handling will be performed. The default value will be **LC_FASTMSG=true** in the **/etc/environment** file.

LC_MESSAGES

Specifies the locale to use for **LC_MESSAGES** category information. The **LC_MESSAGES** category determines rules governing affirmative and negative responses and the locale (language) for messages and menus.

Application developers who write applications that do not display multibyte characters on a terminal should make sure the **LC_MESSAGES** value is not set to **C@1ft**. If necessary, disable the setting with the **putenv("LC_MESSAGES=")** subroutine. The result is output that uses translated message catalogs. **C@1ft** is disabled by login sessions that can display multibyte characters. Processes launched using **cron** or **inittab** retain the **C@1ft** **LC_MESSAGES** value and use the **setlocale()** subroutine to establish the language environment for default messages.

LC_MONETARY

Specifies the locale to use for **LC_MONETARY** category information. The **LC_MONETARY** category determines the rules governing monetary-related formatting.

LC_NUMERIC

Specifies the locale to use for **LC_NUMERIC** category information. The **LC_NUMERIC** category determines the rules governing nonmonetary numeric formatting.

LC_TIME

Specifies the locale to use for **LC_TIME** category information. The **LC_TIME** category determines the rules governing date and time formatting.

LOCPATH

Specifies the search path for localized information, including binary locale files, input methods, and code-set converters.

Note: All **setuid** and **setgid** programs ignore the **LOCPATH** environment variable.

NLSPATH

Specifies the search path for locating message catalog files. This environment variable is used by the Message Facility component of the multicultural support subsystem. See the **catopen** subroutine for more information about expected format of the **NLSPATH** variable.

The environment variables that affect locale selection can be grouped into three priority classes: high, medium, and low. Environment variables in the high priority class are:

- **LC_ALL**
- **LC_COLLATE**
- **LC_CTYPE**

Environment variables in the medium priority class are:

- **LC_MESSAGES**
- **LC_MONETARY**
- **LC_NUMERIC**
- **LC_TIME**

The environment variable in the low priority class is:

- **LANG**

When a locale is requested by the **setlocale** subroutine for a particular category or for all categories, the environment variable settings are queried by their priority level in the following manner:

- If the **LC_ALL** environment variable is set, all six categories use the locale it specified. For example, if the **LC_ALL** environment variable is equal to **en_US** and the **LANG** environment variable is equal to **fr_FR**, a call to the **setlocale** subroutine sets each of the six categories to the **en_US** locale.
- If the **LC_ALL** environment variable is not set, each individual category uses the locale specified by its corresponding environment variable. For example, if the **LC_ALL** environment variable is not set, the **LC_COLLATE** environment variable is set to **de_DE**, and the **LC_TIME** environment variable is set to **fr_CA**, then a call to the **setlocale** subroutine sets the **LC_COLLATE** category to **de_DE** and the **LC_TIME** category to **fr_CA**. Neither environment variable has precedence over the other in this situation.
- If the **LC_ALL** environment variable is not set, and a value for a particular **LC_*** environment variable is not set, the value of the **LANG** environment variable determines the setting for that specific category. For example, if the **LC_ALL** environment variable is not set, the **LC_CTYPE** environment variable is set to **en_US**, the **LC_NUMERIC** environment variable is not set, and the **LANG** environment variable is set to **is_IS**, then a call to the **setlocale** subroutine sets the **LC_CTYPE** category to **en_US** and the **LC_NUMERIC** category to **is_IS**. The **LANG** environment variable specifies the locale for only those categories not previously determined by an **LC_*** environment variable.
- If the **LC_ALL** environment variable is not set, a value for a particular **LC_*** environment variable is not set, and the value of the **LANG** environment variable is not set, the locale for that specific category

defaults to the C locale. For example, if the **LC_ALL** environment variable is not set, the **LC_MONETARY** environment variable is set to **sv_SE**, the **LC_TIME** environment variable is not set, and the **LANG** environment variable is not set, then a call to the **setlocale** subroutine sets the **LC_MONETARY** category to **sv_SE** and the **LC_TIME** category to C.

Environment variables precedence example

The following table shows the current setting of the environment variables and the effect of calling **setlocale(LC_ALL, "")**. The last column indicates the locale setting after **setlocale(LC_ALL, "")** is called.

Table 1. Environment variables precedence example

Environment Variable and Category Names	Value of Environment Variables	Value of Category after Call to setlocale(LC_ALL, "")
LC_COLLATE	de_DE	de_DE
LC_CTYPE	de_DE	de_DE
LC_MONETARY	en_US	en_US
LC_NUMERIC	(unset)	da_DK
LC_TIME	(unset)	da_DK
LC_MESSAGES	(unset)	da_DK
LC_ALL	(unset)	(not applicable)
LANG	da_DK	(not applicable)

Understanding the locale definition source file

Unlike environment variables, which can be set from the command line, locales can only be modified by editing and compiling a locale definition source file.

If a desired locale is not part of the library, a binary version of the locale can be compiled by the **localedef** command. Locale behavior of programs is not affected by a locale definition source file unless the file is first converted by the **localedef** command, and the locale object is made available to the program. The **localedef** command converts source files containing definitions of locales into a run-time format and copies the run-time version to the file specified on the command line, which usually is a locale name. Globalized commands and subroutines can then access the locale information. For information on preparing source files to be converted by the **localedef** command, see **Locale Definition Source File Format** in *AIX Version 7.1 Files Reference*.

Multibyte subroutines

Multibyte subroutines process characters in file-code form. The names of these subroutines usually start with the prefix **mb**. However, some multibyte subroutines do not have this prefix. For example, the **strcoll** and **strxfrm** subroutines process characters in their multibyte form but do not have the **mb** prefix. The following standard C subroutines operate on bytes and can be used to handle multibyte data: **strcmp**, **strcpy**, **strncmp**, **strncpy**, **strcat**, and **strncat**. The standard C search subroutines **strchr**, **strrchr**, **strpbrk**, **strcspn**, **strrchr**, **strspn**, **strstr**, and **strtok** can be used in the following cases:

- Searching or scanning for characters in single-byte code sets
- Searching or scanning for unique code-point range characters in multibyte strings

This section guides programmers in using subroutines when developing portable globalized programs. Use standard Open Group, ISO/ANSI C, and POSIX functions to maximize portability.

Wide character subroutines

Wide character subroutines process characters in process-code form. Wide character subroutines usually start with a **wc** prefix. However, there are exceptions to this rule. For example, the wide character classification functions use an **isw** prefix. To determine if a subroutine is a wide character subroutine,

check if the subroutine prototype defines characters as `wchar_t` data type or `wchar_t` data pointer, or else check whether the subroutine returns a `wchar_t` data type. There are some exceptions to this rule. For example, the wide character classification subroutines accept `wint_t` data type values.

This section guides programmers in using subroutines when developing portable globalized programs. Use standard Open Group, ISO/ANSI C, and POSIX functions to maximize portability.

Bidirectionality and character shaping

An globalized program may need to handle bidirectionality of text and character shaping.

Bidirectionality (BIDI) occurs when texts of different direction orientation appear together. For example, English text is read from left to right. Hebrew text is read from right to left. If both English and Hebrew texts appear on the same line, the text is bidirectional.

Character shaping occurs when the shape of a character is dependent on its position in a line of text. In some languages, such as Arabic, characters have different shapes depending on their position in a string and on the surrounding characters.

Related concepts:

“Layout (bidirectional text and character shaping) overview” on page 163

Bidirectional (BIDI) text results when texts of different direction orientation appear together. For example, English text is read from left to right. Arabic and Hebrew texts are read from right to left. If both English and Hebrew texts appear on the same line, the text is bidirectional.

Code set independence

The system needs certain information about code sets to communicate with the external environment. This information is hidden by the code set-independent library subroutines (globalization library). These subroutines pass information to the code set-dependent functions. Because multicultural support subroutines handle the necessary code set information, you do not need explicit knowledge of any code set when you write programs that process characters. This programming technique is called *code set independence*.

Related concepts:

“Multicultural support sample program” on page 220

This section contains a sample program fragment, `my_example.c`, which illustrates globalization through code set independent programming.

Determining maximum number of bytes in code sets

You can use the `MB_CUR_MAX` macro to determine the maximum number of bytes in a multibyte character for the code set in the current locale. The value of this macro is dependent on the current setting of the `LC_CTYPE` category. Because the locale can differ between processes, running the `MB_CUR_MAX` macro in different processes or at different times may produce different results. The `MB_CUR_MAX` macro is defined in the `stdlib.h` header file.

You can use the `MB_LEN_MAX` macro to determine the maximum number of bytes in any code set that is supported by the system. This macro is defined in the `limits.h` header file.

Detemining character and string display widths

The `_max_disp_width` macro is operating-system-specific, and its use should be avoided in portable applications. If portability is not important, you can use the `_max_disp_width` macro to determine the maximum number of display columns required by a single character in the code set in the current locale. The value of this macro is dependent on the current setting of the `LC_CTYPE` category. If the value of this is 1 (one), all characters in the current code set require only one display column width on output.

When both `MB_CUR_MAX` and `_max_disp_width` are set to 1 (one), you can use the `strlen` subroutine to determine the display column width needed for a string. When `MB_CUR_MAX` is greater than one, use the `wcswidth` subroutine to find the display column width of the string.

The `wcswidth` and `wcwidth` wide-character display-width subroutines do not have corresponding multibyte functions. The `wcswidth` subroutine does not indicate how many characters can be displayed in the space available on a display. The `wcwidth` subroutine is useful for this purpose. This subroutine must be called repeatedly on a wide-character string to find out how many characters can be displayed in the available positions on the display.

Exceptions to code set knowledge: unique code-point range

Because of the way the supported code sets are organized, there is one exception to the statement: "No knowledge of the underlying code set can be assumed in a program."

When a multibyte character string is searched for any character within the unique code-point range (for example, the `.` (period) character), it is not necessary to convert the string to process code form. It is sufficient to just look for that character (`.`) by examining each byte. This exception enables the kernel and utilities to search for the special characters `.` and `/` while parsing file names. If a program searches for any of the characters in the unique code-point range, the standard string functions that operate on bytes (such as the `strchr` subroutine), should be used. For a list of the characters in the unique code-point range, see "ASCII characters" on page 51.

File name matching

POSIX.2 defines the `fnmatch` subroutine to be used for file name matching. An application can use the `fnmatch` subroutine to read a directory and apply a pattern against each entry. For example, the `find` utility can use the `fnmatch` subroutine. The `pax` utility can use the `fnmatch` subroutine to process its pattern operands. Applications that must match strings in a similar fashion can use the `fnmatch` subroutine.

Radix character handling

Note that the radix character, as obtained by `nl_langinfo(RADIXCHAR)`, is a pointer to a string. It is possible that a locale may specify this as a multibyte character or as a string of characters. However, in AIX, a simplifying assumption is made that the `RADIXCHAR` is a single-byte character.

Programming model

The programming model presented here highlights changes you need to make when an existing program is globalized or when a new program is developed:

- Provide complete globalization. Do not assume that characters have any specific properties. Determine the properties dynamically by using the appropriate interfaces. Do not assume properties of code sets, except for the ASCII characters with code points in the unique code-point range.
- Make programs code set-independent. Programs should not assume single-byte, double-byte, or multibyte encoding of any sort. Data can be processed in either process-code or file-code form by using the appropriate subroutines.
- Provide interaction with the kernel in file-code form only. The kernel does not handle process codes.
- The multicultural support subroutine library can handle processing based on file code as well as processing based on process code.

Note: Several subroutines based on process-code form do not have corresponding subroutines based on file code form. Due to this asymmetry, it may be necessary to convert strings to process-code form and invoke the appropriate process-code subroutines.

- Some libraries may not provide processing in process-code form. An application needing these libraries must use file-codes when invoking functions from them.

- Programs can process characters either in process-code form or file-code form. It is possible to write code set-independent programs using both methods.

Subroutines for multicultural support

This section guides programmers in using subroutines when developing portable globalized programs. Use standard Open Group, ISO/ANSI C, and POSIX functions to maximize portability.

Note: Do not use the layout subroutines in the **libi18n.a** library unless the application is doing presentation types of services. Most applications deal with logically ordered text.

“List of multicultural support subroutines” on page 180

The multicultural support subroutines are used for handling locale-specific information, manipulating wide characters and multibyte characters, and using regular expressions.

“List of regular expression subroutines” on page 184

Locale subroutines

Programs that perform locale-dependent processing, including user messages, must call the **setlocale** subroutine at the beginning of the program. This call is the first executable statement in the **main** program. Programs that do not call the **setlocale** subroutine in this way inherit the C or POSIX locale. Such programs perform as in the C locale, regardless of the setting of the **LC_*** and **LANG** environment variables.

Other subroutines are provided to determine the current settings for locale data formatting.

The locale of a process determines the way that character collation, character classification, date and time formatting, numeric punctuation, monetary punctuation, and message output are handled. The following section describes how to set and access information about the current locale in a program by using multicultural support.

Related concepts:

“Setting the Locale”

Every globalized program must set the current locale using the **setlocale** subroutine. This subroutine allows a process to change or query the current locale by accessing locale databases.

Setting the Locale

Every globalized program must set the current locale using the **setlocale** subroutine. This subroutine allows a process to change or query the current locale by accessing locale databases.

When a process is started, its current locale is set to the C or POSIX locale. A program that depends on locale data not defined in the C or POSIX locale must invoke the **setlocale** subroutine in the following manner before using any of the locale-specific information:

```
setlocale(LC_ALL, "");
```

Related concepts:

“Locale subroutines” on page 13

Programs that perform locale-dependent processing, including user messages, must call the **setlocale** subroutine at the beginning of the program. This call is the first executable statement in the **main** program. Programs that do not call the **setlocale** subroutine in this way inherit the C or POSIX locale. Such programs perform as in the C locale, regardless of the setting of the **LC_*** and **LANG** environment variables.

“Program operation checklist” on page 174

Accessing locale information

The following subroutines provide access to information defined in the current locale as determined by the most recent call to the **setlocale** subroutine:

localeconv

Provides access to locale information defined in the **LC_MONETARY** and **LC_NUMERIC** categories of the current locale. The **localeconv** subroutine retrieves information about these categories, places the information in a structure of type **lconv** as defined in the **locale.h** file, and returns a pointer to this structure.

nl_langinfo

Returns a pointer to a null-terminated string containing information defined in the **LC_CTYPE**, **LC_MESSAGES**, **LC_MONETARY**, **LC_NUMERIC**, and **LC_TIME** categories of the current locale.

rpmatch

Tests for positive and negative responses, which are specified in the **LC_MESSAGES** category of the current locale. Responses can be regular expressions, as well as simple strings. The **rpmatch** subroutine is not an industry-standard subroutine, portable applications should not assume that this subroutine is available.

The **localeconv** and **nl_langinfo** subroutines do not provide access to all **LC_*** categories.

The current locale setting for a category can be obtained by: **setlocale(Category, (char*)0)**. The return value is a string specifying the current locale for *Category*. The following example determines the current locale setting for the **LC_CTYPE** category:

```
char *ctype_locale; ctype_locale = setlocale(LC_CTYPE, (char*)0);
```

Examples

This section contains examples of the subroutines.

- The following example uses the **setlocale** subroutine to change the locale from the default C locale to the locale specified by the environment variables, consistent with the hierarchy of the locale environment variables:

```
#include <locale.h>
main()
{
    char *p;

    p = setlocale(LC_ALL, "");

    /*
```

```

    ** The program will have the locale as set by the
    ** LC_* and LANG variables.
    */
}

```

- The following example uses the **setlocale** subroutine to obtain the current locale setting for the **LC_COLLATE** category:

```

#include <stdio.h>
#include <locale.h>

main()
{
    char *p;

    /* set the current locale to what is specified */
    p = setlocale(LC_ALL, "");
    /* The current locale settings for all the
    ** categories is pointed to by p
    */

    /*
    ** Find the current setting for the
    ** LC_COLLATE category
    */
    p = setlocale(LC_COLLATE, NULL);
    /*
    ** p points to a string containing the current locale
    ** setting for the LC_COLLATE category.
    */

}

```

- The following example uses the **setlocale** subroutine to obtain the current locale setting and saves it for later use. This action allows the program to temporarily change the locale to a new locale. After processing is complete, the locale can be returned to its original state.

```

#include <stdio.h>
#include <locale.h>
#include <string.h>

#define NEW_LOCALE "MY_LOCALE"

main()
{
    char *p, *save_locale;

    p = setlocale(LC_ALL, "");
    /*
    ** Initiate locale. p points to the current locale
    ** setting for all the categories
    */

    save_locale = (char *)malloc(strlen(p) + 1);
    strcpy(save_locale, p);
    /* Save the current locale setting */
    p = setlocale(LC_ALL, NEW_LOCALE);
    /* Change to new locale */

    /*
    ** Do processing ...
    */

    /* Change back to old locale */
    p = setlocale(LC_ALL, save_locale); /* Restore old locale */

    free(save_locale); /* Free the memory */
}

```

- The following example uses the **setlocale** subroutine to set the **LC_MESSAGES** category to the locale determined by the environment variables. All other categories remain set to the C locale.

```
#include <locale.h>

main()
{
    char *p;

    /*
    ** The program starts in the C locale for all categories.
    */

    p = setlocale(LC_MESSAGES, "");

    /*
    ** At this time the LC_COLLATE, LC_CTYPE, LC_NUMERIC,
    ** LC_MONETARY, LC_TIME will be in the C locale.
    ** LC_MESSAGES will be set to the current locale setting
    ** as determined by the environment variables.
    */
}
```

- The following example uses the **localeconv** subroutine to obtain the decimal-point setting for the current locale:

```
#include <locale.h>

main()
{
    struct lconv *ptr;
    char *decimal;

    (void)setlocale(LC_ALL, "");
    ptr = localeconv();
    /*
    ** Access the data obtained. For example,
    ** obtain the current decimal point setting.
    */
    decimal = ptr->decimal_point;
}
```

- The following example uses the **nl_langinfo** subroutine to obtain the date and time format for the current locale:

```
#include <langinfo.h>
#include <locale.h>
main()
{
    char *ptr;
    (void)setlocale(LC_ALL, "");
    ptr = nl_langinfo(D_T_FMT);
}
```

- The following example uses the **nl_langinfo** subroutine to obtain the radix character for the current locale:

```
#include <langinfo.h>
#include <locale.h>

main()
{
    char *ptr;
    (void)setlocale(LC_ALL, ""); /* Set the program's locale */
    ptr = nl_langinfo(RADIXCHAR); /* Obtain the radix character*/
}
```

- The following example uses the **nl_langinfo** subroutine to obtain the setting of the currency symbol for the current locale:

```

#include <langinfo.h>
#include <locale.h>

main()
{
    char *ptr;
    (void)setlocale(LC_ALL, ""); /* Set the program's locale */
    ptr = nl_langinfo(CRNCYSTR); /* Obtain the currency string*/
    /* The currency string will be "$" in the U. S. locale. */
}

```

- The following example uses the `rpmatch` subroutine to obtain the setting of affirmative and negative response strings for the current locale:

The affirmative and negative responses as specified in the locale database are no longer simple strings; they can be regular expressions. For example, the `yesexpr` can be the following regular expression, which will accept an upper or lower case letter `y`, followed by zero or more alphabetic characters; or the character `0` followed by `K`. Thus, `yesexpr` may be the following regular expression:

```

([yY][:alpha:]*|OK)

```

The standards do not contain a subroutine to retrieve and compare this information. You can use the AIX-specific `rpmatch(const char *response)` subroutine.

```

#include <stdio.h>
#include <langinfo.h>
#include <locale.h>
#include <regex.h>

int rpmatch(const char *);
/*
** Returns 1 if yes response, 0 if no response,
** -1 otherwise
*/

main()
{
    int ret;
    char *resp;

    (void)setlocale(LC_ALL, "");

    do {
        /*
        ** Obtain the response to the query for yes/no strings.
        ** The string pointer resp points to this response.
        ** Check if the string is yes.
        */
        ret = rpmatch(resp);

        if(ret == 1){
            /* Response was yes. */
            /* Process accordingly. */
        }else if(ret == 0){
            /* Response was negative. */
            /* Process negative response. */
        }else if(ret<0){
            /* No match with yes/no occurred. */
            continue;
        }
    }while(ret <0);
}

```

- The following example provides a method of implementing the `rpmatch` subroutine. Note that most applications should use the `rpmatch` subroutine in `libc`. The following implementation of the `rpmatch` subroutine is for illustration purposes only.

Note that `nl_langinfo(YESEXPR)` and `nl_langinfo(NOEXPR)` are used to obtain the regular expressions for the affirmative and negative responses respectively.

```

#include <langinfo.h>
#include <regex.h>
/*
** rpmatch() performs comparison of a string to a regular expression
** using the POSIX.2 defined regular expression compile and match
** functions. The first argument is the response from the user and the
** second string is the current locale setting of the regular expression.
*/
int rpmatch( const char *string)

{
    int status;
    int retval;
    regex_t re;
    char *pattern;

    pattern = nl_langinfo(YESEXP);
    /* Compile the regular expression pointed to by pattern. */
    if( ( status = regcomp( &re, pattern, REG_EXTENDED | REG_NOSUB )) != 0 ){
        retval = -2; /*-2 indicates yes expr compile error */
        return(retval);
    }
    /* Match the string with the compiled regular expression. */
    status = regexec( &re, string, (size_t)0, (regmatch_t *)NULL, 0);
    if(status == 0){
        retval = 1; /* Yes match found */
    }else{ /* Check for negative response */
        pattern = nl_langinfo(NOEXPR);
        if( ( status = regcomp( &re, pattern,
            REG_EXTENDED | REG_NOSUB )) != 0 ){
            retval = -3; /*-3 indicates no compile error */
            return(retval);
        }
        status = regexec( &re, string, (size_t)0,
            (regmatch_t *)NULL, 0);
        if(status == 0)
            retval = 0; /* Negative response match found */
    }else
        retval = -1; /* The string did not match yes or no
            response */

    regfree(&re);
    return(retval);
}

```

Time formatting subroutines

Programs that need to format time into wide character code strings can use the **wcsftime** subroutine. Programs that need to convert multibyte strings into an internal time format can use the **strptime** subroutine.

In addition to the **strptime** subroutine defined in the C programming language standard, X/Open Portability Guide Issue 4 defines the following time formatting subroutines:

wcsftime

Formats time into wide character code strings

strptime

Converts a multibyte string into an internal time format

Examples

The following example uses the **wcsftime** subroutine to format time into a wide character string:

Often begins with a definition, answering the question, "What is this?"

```

#include <stdio.h>
#include <langinfo.h>
#include <locale.h>
#include <time.h>

main()
{
    wchar_t timebuf[BUFSIZE];
    time_t clock = time( (time_t*) NULL);
    struct tm *tmptr = localtime(&clock);

    (void)setlocale(LC_ALL, "");

    wcsftime(
        timebuf,      /* Time string output buffer */
        BUFSIZ,      /*Maximum size of output string */
        nl_langinfo(D_T_FMT), /* Date/time format */
        tmptr        /* Pointer to tm structure */
    );

    printf("%S\n", timebuf);
}

```

The following example uses the `strptime` subroutine to convert a formatted time string to internal format:

```

#include <langinfo.h>
#include <locale.h>
#include <time.h>

main(int argc, char **argv)
{
    struct tm tm;

    (void)setlocale(LC_ALL, "");

    if (argc != 2) {
        ... /* Error handling */
    }
    if (strptime(
        argv[1],      /* Formatted time string */
        nl_langinfo(D_T_FMT), /* Date/time format */
        &tm          /* Address of tm structure */
    ) == NULL) {
        ... /* Error handling */
    }
    else {
        ... /* Other Processing */
    }
}

```

Monetary formatting subroutines

Programs that need to specify or access monetary quantities can call the `strfmon` subroutine.

Although the C programming language standard in conjunction with POSIX provides a means of specifying and accessing monetary information, these standards do not define a subroutine that formats monetary quantities. The XPG4 `strfmon` subroutine provides the facilities to format monetary quantities. No defined subroutine converts a formatted monetary string into a numeric quantity suitable for arithmetic. Applications that need to do arithmetic on monetary quantities may do so after processing the locale-dependent monetary string into a number. The culture-specific monetary formatting information is specified by the `LC_MONETARY` category. An application can obtain information pertaining to the monetary format and the currency symbol by calling the `localeconv` subroutine.

Euro currency support

The `strfmon` subroutine uses the information from the locale's `LC_MONETARY` category to determine the correct monetary format for the given language/territory. Locales can handle both the traditional national currencies by using the `@preeuro` modifier, as well as the common European currency (euro). Each European country that uses the euro will have an additional `LC_MONETARY` definition with the `@preeuro` modifier appended. This alternate format is invoked when specified through the locale environment variables, or with the `setlocale` subroutine.

To use the French locale, UTF-8 code set environment, and euro as the monetary unit, set:

```
LANG=FR_FR
LC_MONETARY=FR_FR@preeuro
```

Users should **not** attempt to set `LANG=FR_FR@preeuro`, because the `@preeuro` variant for locale categories other than `LC_MONETARY` is undefined.

Examples

The following example uses the `strfmon` subroutine and accepts a format specification and an input value. The input value is formatted according to the input format specification.

```
#include <monetary.h>
#include <locale.h>
#include <stdio.h>

main(int argc, char **argv)
{
    char bfr[256], format[256];
    int match; ssize_t size;
    float value;

    (void) setlocale(LC_ALL, "");

    if (argc != 3){
        ...          /* Error handling */
    }
    match = sscanf(argv[1], "%f", &value);
    if (!match) {
        ...          /* Error handling */
    }
    match = sscanf(argv[2], "%s", format);
    if (!match) {
        ...          /*Error handling */
    }
    size = strfmon(bfr, 256, format, value);
    if (size == -1) {
        ...          /* Error handling */
    }
    printf ("Formatted monetary value is: %s\n", bfr);
}
```

The following table provides examples of other possible conversion specifications and the outputs for 12345.67 and -12345.67 in a U.S. English locale:

Conversion Specification	Output	Output
%n	\$12,345.67 -\$12,345.67\$12	Default formatting
%15n	\$12,345.67 -\$12,345.67	Right justifies within a 15-character field.
##6n	\$ 12,345.67 -\$ 12,345.67	Aligns columns for values up to 999,999.
%=#8n	\$***12,345.67 -\$***12,345.67	Specifies a fill character.
%=#8n	\$000012,345.67 -\$000012,345.67	Fill characters do not use grouping.
^#6n	\$ 12345.67 -\$ 12345.67	Disables the thousands separator.
^#6.0n	12346 -\$ 12346	Rounds off to whole units.
^#6.3n	\$ 12345.670 -\$ 12345.670	Increases the precision.
%(#6n	\$ 12,345.67 (\$ 12,345.67)	Uses an alternate positive or negative style.
%!(#6n	12,345.67 (12,345.67)	Disables the currency symbol

The following example converts a monetary value into a numeric value. The monetary string is pointed to by input, and the result of converting it into numeric form is stored in the string pointed to by output. Assume that input and output are initialized.

```

char *input; /* the input multibyte string containing the monetary string */
char *output; /* the numeric string obtained from the input string */
wchar_t src_string[SIZE], dest_string[SIZE];
wchar_t *monetary, *numeric;
wchar_t mon_decimal_point, radixchar;
wchar_t wc;
localeconv *lc;

/* Initialize input and output to point to valid buffers as appropriate. */
/* Convert the input string to process code form*/
retval = mbstowcs(src_string, input, SIZE);
/* Handle error returns */

monetary = src_string;
numeric = dest_string;
lc = localeconv();
/* obtain the LC_MONETARY and LC_NUMERIC info */

/* Convert the monetary decimal point to wide char form */
retval = mbtowlc( &mon_decimal_point, lc->mon_decimal_point,
MB_CUR_MAX);
/* Handle any error case */

/* Convert the numeric decimal point to wide char form */
retval = mbtowlc( &radixchar, lc->decimal_point, MB_CUR_MAX);
/* Handle error case */
/* Assuming the string is converted first into wide character
** code form via mbstowcs, monetary points to this string.
*/
/* Pick up the numeric information from the wide character
** string and copy it into a temp buffer.
*/
while(wc = *monetary++){
    if(iswdigit(wc))
        *numeric++ = wc;
    else if( wc == mon_decimal_point)
        *numeric++=radixchar;
}
*numeric = 0;
/* dest_string has the numeric value of the monetary quantity. */
/* Convert the numeric quantity into multibyte form */
retval = wcstombs( output, dest_string, SIZE);
/* Handle any error returns */
/* Output contains a numeric value suitable for atof conversion. */

```

Multibyte and wide character subroutines

The external representation of data is referred to as the *file code* representation of a character. When file code data is created in files or transferred between a computer and its I/O devices, a single character may be represented by one or several bytes. For processing strings of such characters, it is more efficient to convert these codes into a uniform-length representation. This converted form is intended for internal processing of characters. The internal representation of data is referred to as the *process code* or *wide character code* representation of the character.

Multicultural support globalization of programs is a blend of multibyte and wide character subroutines. A *multibyte* subroutine uses multibyte character sets. A *wide character* subroutine uses wide character sets. Multibyte subroutines have an **mb** prefix. Wide character subroutines have a **wc** prefix. The corresponding string-handling subroutines are indicated by the **mbs** and **wcs** prefixes, respectively. Deciding when to use multibyte or wide character subroutines can be made only after careful analysis.

Multibyte code and character code conversion subroutines

The globalized environment of multicultural support blends multibyte and wide character subroutines. The decision of when to use wide character or multibyte subroutines can be made only after careful analysis.

If a program primarily uses multibyte subroutines, it may be necessary to convert the multibyte character codes to wide character codes before certain wide character subroutines can be used. If a program uses wide character subroutines, data may need to be converted to multibyte form when invoking subroutines. Both methods have drawbacks, depending on the program in use and the availability of standard subroutines to perform the required processing. For instance, the wide character display-column-width subroutine has no corresponding standard multibyte subroutine.

If a program can process its characters in multibyte form, this method should be used instead of converting the characters to wide character form.

Attention: The conversion between multibyte and wide character code depends on the current locale setting. Do not exchange wide character codes between two processes, unless you have knowledge that each locale that might be used handles wide character codes in a consistent fashion. With the exception of locales based on the IBM-eucTW code set, AIX locales use the Unicode character value as a wide character code.

Multibyte code to wide character code conversion subroutines:

The following subroutines are used when converting from multibyte code to wide character code:

mblen Determines the length of a multibyte character. Do not use `p++` to increment a pointer in a multibyte string. Use the **mblen** subroutine to determine the number of bytes that compose a character.

mbstowcs

Converts a multibyte string to a wide character string.

mbtowc

Converts a multibyte character to a wide character.

Wide character code to multibyte code conversion subroutines:

The following subroutines are used when converting from wide character code to multibyte character code:

wcslen

Determines the number of wide characters in a wide character string.

wcstombs

Converts a wide character string to a multibyte character string.

wctomb

Converts a wide character to a multibyte character.

Examples:

The following example uses the **mbtowc** subroutine to convert a character in multibyte character code to wide character code:

```
main()
{
    char    *s;
    wchar_t wc;
    int     n;

    (void)setlocale(LC_ALL,"");

    /*
    ** s points to the character string that needs to be
    ** converted to a wide character to be stored in wc.
    */
    n = mbtowc(&wc, s, MB_CUR_MAX);

    if (n == -1){
        /* Error handle */
    }
    if (n == 0){
        /* case of name pointing to null */
    }

    /*
    ** wc contains the process code for the multibyte character
    ** pointed to by s.
    */
}
```

The following example uses the **wctomb** subroutine to convert a character in wide character code to multibyte character code:

```
main()
{
    char    *s;
    wchar_t wc;
    int     n;

    (void)setlocale(LC_ALL,"");

    /*
    ** s points to the character string that needs to be
    ** converted to a wide character to be stored in wc.
    */
    n = mbtowc(&wc, s, MB_CUR_MAX);

    if (n == -1){
        /* Error handle */
    }
    if (n == 0){
        /* case of name pointing to null */
    }

    /*
    ** wc contains the process code for the multibyte character
    ** pointed to by s.
    */
}
```

The following example uses the `mblen` subroutine to find the byte length of a character in multibyte character code:

```
#include <stdlib.h>
#include <locale.h>

main
{
    char *name = "h";
    int n;

    (void)setlocale(LC_ALL, "");

    n = mblen(name, MB_CUR_MAX);
    /*
    ** The count returned in n is the multibyte length.
    ** It is always less than or equal to the value of
    ** MB_CUR_MAX in stdlib.h
    */
    if(n == -1){
        /* Error Handling */
    }
}
```

The following example obtains a previous character position in a multibyte string. If you need to determine the previous character position, starting from a current character position (not a random byte position), step through the buffer starting at the beginning. Use the `mblen` subroutine until the current character position is reached, and save the previous character position to obtain the needed character position.

```
char buf[];      /* contains the multibyte string */
char *cur,      /* points to the current character position */
char *prev,     /* points to previous multibyte character */
char *p;        /* moving pointer */

/* initialize the buffer and pointers as needed */
/* loop through the buffer until the moving pointer reaches
** the current character position in the buffer, always
** saving the last character position in prev pointer */
p = prev = buf;

/* cur points to a valid character somewhere in buf */
while(p < cur){
    prev = p;
    if( (i=mblen(p, mbcurmax)) <= 0){
        /* invalid multibyte character or null */
        /* You can have a different error handling
        ** strategy */
        p++; /* skip it */
    } else {
        p += i;
    }
}
/* prev will point to the previous character position */

/* Note that if( prev == cur), then it means that there was
** no previous character. Also, if all bytes up to the
** current character are invalid, it will treat them as
** all valid single-byte characters and this may not be what
** you want. One may change this to handle another method of
** error recovery. */
```

The following example uses of the `mbstowcs` subroutine to convert a multibyte string to wide character string:

```

#include <stdlib.h>
#include <locale.h>

main()
{
    char    *s;
    wchar_t *pwcs;
    size_t  retval, n;

    (void)setlocale(LC_ALL, "");

    n = strlen(s) + 1;          /*string length + terminating null */

    /* Allocate required wchar array */
    pwcs = (wchar_t *)malloc(n * sizeof(wchar_t) );
    retval = mbstowcs(pwcs, s, n);
    if(retval == -1){

        /* Error handle */
        }
        /*
        ** pwcs contains the wide character string.
        */
    }
}

```

The following example illustrates the problems with using the **mbstowcs** subroutine on a large block of data for conversion to wide character form. When it encounters a multibyte that is not valid, the **mbstowcs** subroutine returns a value of -1 but does not specify where the error occurred. Therefore, the **mbtowc** subroutine must be used repeatedly to convert one character at a time to wide character code.

Note: Processing in this manner can considerably slow program performance.

During the conversion of single-byte code sets, there is no possibility for partial multibytes. However, during the conversion of multibyte code sets, partial multibytes are copied to a save buffer. During the next call to the **read** subroutine, the partial multibyte is prefixed to the rest of the byte sequence.

Note: A null-terminated wide character string is obtained. Optional error handling can be done if an instance of an invalid byte sequence is found.

```

#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main(int argc, char *argv[])
{
    char    *curp, *cure;
    int     bytesread, bytestoconvert, leftover;
    int     invalid_multibyte, mbcnt, wcnt;
    wchar_t *pwcs;
    wchar_t wbuf[BUFSIZ+1];
    char    buf[BUFSIZ+1];
    char    savebuf[MB_LEN_MAX];
    size_t  mb_cur_max;
    int     fd;

    /*
    ** MB_LEN_MAX specifies the system wide constant for
    ** the maximum number of bytes in a multibyte character.
    */

    (void)setlocale(LC_ALL, "");
    mb_cur_max = MB_CUR_MAX;

    fd = open(argv[1], 0);
    if(fd < 0){

```

```

    /* error handle */
}

leftover = 0;
if(mb_cur_max==1){ /* Single byte code sets case */
    for(;;){
        bytesread = read(fd, buf, BUSIZ);
        if(bytesread <= 0)
            break;
        mbstowcs(wbuf, buf, bytesread+1);
        /* Process using the wide character buffer */
    }
    /* File processed ... */
    exit(0); /* End of program */
}else{ /* Multibyte code sets */
    leftover = 0;

    for(;;) {
        if(leftover)
            strncpy(buf, savebuf ,leftover);
        bytesread=read(fd,buf+leftover, BUFSIZ-leftover);
        if(bytesread <= 0)
            break;

        buf[leftover+bytesread] = '\0';
        /* Null terminate string */
        invalid_multibyte = 0;
        bytestoconvert = leftover+bytesread;
        cure= buf+bytestoconvert;
        leftover=0;
        pwcs = wbuf;
        /* Stop processing when invalid mbyte found. */
        curp= buf;

        for(;curp<cure;){
            mbcnt = mbtowc(pwcs,curp, mb_cur_max);
            if(mbcnt>0){
                curp += mbcnt;
                pwcs++;
                continue;
            }else{
                /* More data needed on next read*/
                if ( cure-curp<mb_cur_max){
                    leftover=cure-curp;
                    strncpy(savebuf,curp,leftover);
                    /* Null terminate before partial mbyte */
                    *curp=0;
                    break;
                }else{
                    /*Invalid multibyte found */
                    invalid_multibyte =1;
                    break;
                }
            }
        }
        if(invalid_multibyte){ /*error handle */
        }
        /* Process the wide char buffer */
    }
}
}

```

The following example uses the **wcstombs** and **wcslen** subroutines to convert a wide character string to multibyte form:

```

#include <stdlib.h>
#include <locale.h>

main()
{
    wchar_t *pwcs; /* Source wide character string */
    char *s;      /* Destination multibyte character string */
    size_t n;
    size_t retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** Calculate the maximum number of bytes needed to
    ** store the wide character buffer in multibyte form in the
    ** current code page and malloc() the appropriate storage,
    ** including the terminating null.
    */
    s = (char *) malloc( wcslen(pwcs) * MB_CUR_MAX + 1 );
    retval= wcstombs( s, pwcs, n);
    if( retval == -1) {
        /* Error handle */
        /* s points to the multibyte character string. */
    }
}

```

Wide character classification subroutines

The majority of wide character classification subroutines are similar to traditional character classification subroutines, except that wide character classification subroutines operate on a **wchar_t** data type argument passed as a **wint_t** data type argument.

Related concepts:

“Program operation checklist” on page 174

Generic wide character classification subroutines:

In the globalization environment, you need the ability to create new character class properties. For example, several properties are defined for Japanese characters that are not applicable to the English language. As more languages are supported, a framework enabling applications to deal with a varying number of character properties is needed.

The **wctype** and **iswctype** subroutines allow handling of character classes in a general fashion. These subroutines are used to allow for both user-defined and language-specific character classes.

To create new character classifications for use with the **wctype** and **iswctype** subroutines, create a new character class in the **LC_CTYPE** category and generate the locale using the **localedef** command. A user application obtains this locale data with the **setlocale** subroutine. The program can then access the new classification subroutines by using the **wctype** subroutine to get the **wctype_t** property handle. It then passes to the **iswctype** subroutine both the property handle and the wide character code of the character to be tested.

The following subroutines are used for wide character classification:

wctype

Obtains handle for character property classification.

iswctype

Tests for character property.

Standard wide character classification subroutines:

The **isw*** subroutines determine various aspects of a standard wide character classification. The **isw*** subroutines also work with single-byte code sets. Use the **isw*** subroutines in preference to the **wctype**

and **iswctype** subroutines. Use the **wctype** and **iswctype** subroutines only for extended character class properties (for example, Japanese language properties).

When using the wide character functions to convert the case in several blocks of data, the application must convert characters from multibyte to wide character code form. Because this can affect performance in single-byte code set locales, consider providing two conversion paths in your application. The traditional path for single-byte code set locales would convert case using the **isupper**, **islower**, **toupper**, and **tolower** subroutines. The alternate path for multibyte code set locales would convert multibyte characters to wide character code form and convert case using the **iswupper**, **iswlower**, **towupper** and **towlower** subroutines. When converting multibyte characters to wide character code form, an application needs to handle special cases where a multibyte character may split across successive blocks.

The following is a list of standard wide character classification subroutines:

iswalnum

Tests for alphanumeric character classification

iswcntrl

Tests for alphabetic character classification.

iswalpha

Tests for control character classification.

iswdigit

Tests for digit character classification.

iswgraph

Tests for graphic character classification.

iswlower

Tests for lowercase character classification.

iswprint

Tests for printable character classification.

iswpunct

Tests for punctuation character classification.

iswspace

Tests for space character classification.

iswupper

Tests for uppercase character classification.

iswxdigit

Tests for hexadecimal-digit character classification.

Wide character case conversion subroutines:

The following subroutines convert cases for wide characters. The action of wide character case conversion subroutines is affected by the definition in the **LC_CTYPE** category for the current locale.

towlower

Converts an uppercase wide character to a lowercase wide character.

towupper

Converts a lowercase wide character to an uppercase wide character.

Example:

The following example uses the **wctype** subroutine to test for the **NEW_CLASS** character classification:

```

#include <ctype.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wint_t    wc;
    int       retval;
    wctype_t  chandle;

    (void)setlocale(LC_ALL,"");
    /*
    ** Obtain the character property handle for the NEW_CLASS
    ** property.
    */
    chandle = wctype("NEW_CLASS") ;
    if(chandle == (wctype_t)0){
        /* Invalid property. Error handle. */
    }
    /* Let wc be the wide character code for a character */
    /* Test if wc has the property of NEW_CLASS */
    retval = iswctype( wc, chandle );
    if( retval > 0 ) {
        /*
        ** wc has the property NEW_CLASS.
        */
    }else if(retval == 0) {
        /*
        ** The character represented by wc does not have the
        ** property NEW_CLASS.
        */
    }
}

```

Wide character display column width subroutines

When characters are displayed or printed, the number of columns occupied by a character may differ. For example, a Kanji character (Japanese language) may occupy more than one column position. The number of display columns required by each character is part of the multicultural support locale database. The **LC_CTYPE** category defines the number of columns needed to display a character.

No standard multibyte display-column-width subroutines exist. For portability, convert multibyte codes to wide character codes and use the required wide character display-width subroutines. However, if the **__max_disp_width** macro (defined in the **stdlib.h** file) is set to 1 and a single-byte code set is in use, then the display-column widths of all characters (except tabs) in the code set are the same, and are equal to 1. In this case, the **strlen** (*string*) subroutine gives the display column width of the specified string, as shown in the following example:

```

#include <stdlib.h>
    int display_column_width; /* number of display columns */
    char *s;                 /* character string */
    ....
    if((MB_CUR_MAX == 1) && (__max_disp_width == 1)){
        display_column_width = strlen(s);
        /* s is a string pointer */
    }

```

The following subroutines find the display widths for wide character strings:

wcswidth

Determines the display width of a wide character string.

wcwidth

Determines the display width of a wide character.

Examples:

The following example uses the `wcwidth` subroutine to find the display column width of a wide character:

```
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wint_t  wc;
    int     retval;

    (void)setlocale(LC_ALL, "");

    /*
    ** Let wc be the wide character whose display width is
    ** to be found.
    */
    retval = wcwidth(wc);
    if(retval == -1){
        /*
        ** Error handling. Invalid or nonprintable
        ** wide character in wc.
        */
    }
}
```

The following example uses the `wcswidth` subroutine to find the display column width of a wide character string:

```
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs;
    int     retval;
    size_t  n;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs point to a wide character null
    ** terminated string.
    ** Let n be the number of wide characters
    ** whose display column width is to be determined.
    */
    retval = wcswidth(pwcs, n);
    if(retval == -1){
        /*
        ** Error handling. Invalid wide or nonprintable
        ** character code encountered in the wide
        ** character string pwcs.
        */
    }
}
```

Multibyte and wide character string collation subroutines

Strings can be compared in the following ways:

- Using the ordinal (binary) values of the characters.
- Using the weights associated with the characters for each locale, as determined by the `LC_COLLATE` category.

Multicultural support uses the second method.

Collation is a locale-specific property of characters. A weight is assigned to each character to indicate its relative order for sorting. A character may be assigned more than one weight. Weights are prioritized as primary, secondary, tertiary, and so forth. The maximum number of weights assigned each character is system-defined.

A process inherits the C locale or POSIX locale at its startup time. When the **setlocale(LC_ALL, "")** subroutine is called, a process obtains its locale based on the **LC_*** and **LANG** environment variables. The following subroutines are affected by the **LC_COLLATE** category and determine how two strings will be sorted in any given locale.

Note: Collation-based string comparisons take a long time because of the processing involved in obtaining the collation values. Perform such comparisons only when necessary. If you need to determine whether two wide character strings are equal, do not use the **wscoll** and **wcsxfrm** subroutines; use the **wscmp** subroutine instead.

The following subroutines compare multibyte character strings:

strcoll Compares the collation weights of multibyte character strings.

strxfrm

Converts a multibyte character string to values representing character collation weights.

The following subroutines compare wide character strings:

wscoll

Compares the collation weights of wide character strings.

wcsxfrm

Converts a wide character string to values representing character collation weights.

Examples:

The following example uses the **wscoll** subroutine to compare two wide character strings based on their collation weights:

```
#include <stdio.h>
#include <string.h>
#include <locale.h>
#include <stdlib.h>

extern int errno;

main()
{
    wchar_t *pwcs1, *pwcs2;
    size_t n;

    (void)setlocale(LC_ALL, "");

    /* set it to zero for checking errors on wscoll */
    errno = 0;
    /*
    ** Let pwcs1 and pwcs2 be two wide character strings to
    ** compare.
    */
    n = wscoll(pwcs1, pwcs2);
    /*
    ** If errno is set then it indicates some
    ** collation error.
    */
    if(errno != 0){
        /* error has occurred... handle error ...*/
    }
}
```

The following example uses the **wcsxfrm** subroutine to compare two wide character strings based on collation weights:

Note: Determining the size *n* (where *n* is a number) of the transformed string, when using the **wcsxfrm** subroutine, can be accomplished in one of the following ways:

- For each character in the wide character string, the number of bytes for possible collation values cannot exceed the **COLL_WEIGHTS_MAX * sizeof(wchar_t)** value. This value, multiplied by the number of wide character codes, gives the buffer length needed. To the buffer length add 1 for the terminating wide character null. This strategy may slow down performance.
- Estimate the byte-length needed. If the previously obtained value is not enough, increase it. This may not satisfy all strings but gives maximum performance.
- Call the **wcsxfrm** subroutine twice: first to find the value of *n*, and a second time to transform the string using this *n* value. This strategy slows down performance because the **wcsxfrm** subroutine is called twice. However, it yields a precise value for the buffer size needed to store the transformed string.
-

The method you choose depends on the characteristics of the strings used in the program and the performance objectives of the program.

```
#include <stdio.h>
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2, *pwcs3, *pwcs4;
    size_t n, retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let the string pointed to by pwcs1 and pwcs3 be the
    ** wide character arrays to store the transformed wide
    ** character strings. Let the strings pointed to by pwcs2
    ** and pwcs4 be the wide character strings to compare based
    ** on the collation values of the wide characters in these
    ** strings.
    ** Let n be large enough (say,BUFSIZ) to transform the two
    ** wide character strings specified by pwcs2 and pwcs4.
    **
    ** Note:
    ** In practice, it is best to call wcsxfrm if the wide
    ** character string is to be compared several times to
    ** different wide character strings.
    */

    do {
        retval = wcsxfrm(pwcs1, pwcs2, n);
        if(retval == (size_t)-1){
            /* error has occurred. */
            /* Process the error if needed */
            break;
        }

        if(retval >= n){
            /*
            ** Increase the value of n and use a bigger buffer pwcs1.
            */
        }
    }while (retval >= n);

    do {
```

```

    retval = wcsxfrm(pwcs3, pwcs4, n);
    if (retval == (size_t)-1){
        /* error has occurred. */
        /* Process the error if needed */
        break;

        if(retval >= n){
            /*Increase the value of n and use a bigger buffer pwcs3.*/
        }
    }while (retval >= n);
    retval = wcsncmp(pwcs1, pwcs3);
    /* retval has the result */
}

```

Multibyte and wide character string comparison subroutines

The **stricmp** and **strncmp** subroutines determine if the contents of two multibyte strings are equivalent. If your application needs to know how the two strings differ lexically, use the multibyte and wide character string collation subroutines.

The following multicultural support subroutines compare wide character strings:

Subroutines	Description
wscmp	Compares two wide character strings.
wcsncmp	Compares a specific number of wide character strings.

Example:

The following example uses the **wscmp** subroutine to compare two wide character strings:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2;
    int retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** pwcs1 and pwcs2 point to two wide character
    ** strings to compare.
    */
    retval = wscmp(pwcs1, pwcs2);
    /* pwcs1 contains a copy of the wide character string
    ** in pwcs2
    */
}

```

Wide character string conversion subroutines

The following multicultural support subroutines convert wide character strings to double, long, and unsigned long integers:

Subroutine	Description
wcstod	Converts a wide character string to a double-precision floating point.
wcstol	Converts a wide character string to a signed long integer.
wcstoul	Converts a wide character string to an unsigned long integer.

Before calling the **wcstod**, **wcstoul**, or **wcstol** subroutine, the **errno** global variable must be set to 0. Any error that occurs as a result of calling these subroutines can then be handled correctly.

Examples:

The following example uses the **wcstod** subroutine to convert a wide character string to a double-precision floating point:

```
#include <stdlib.h>
#include <locale.h>
#include <errno.h>

extern int errno;

main()
{
    wchar_t *pwcs, *endptr;
    double  retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs point to a wide character null terminated
    ** string containing a floating point value.
    */
    errno = 0; /* set errno to zero */
    retval = wcstod(pwcs, &endptr);

    if(errno != 0){
        /* errno has changed, so error has occurred */

        if(errno == ERANGE){
            /* correct value is outside range of
            ** representable values. Case of overflow
            ** error
            */

            if((retval == HUGE_VAL) ||
               (retval == -HUGE_VAL)){
                /* Error case. Handle accordingly. */
            }else if(retval == 0){
                /* correct value causes underflow */
                /* Handle appropriately */
            }
        }
    }
    /* retval contains the double. */
}
```

The following example uses the **wcstol** subroutine to convert a wide character string to a signed long integer:

```
#include <stdlib.h>
#include <locale.h>
#include <errno.h>
#include <stdio.h>

extern int errno;
```

```

main()
{
    wchar_t  *pwcs, *endptr;
    long int  retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs point to a wide character null terminated
    ** string containing a signed long integer value.
    */
    errno = 0; /* set errno to zero */
    retval = wcstol(pwcs, &endptr, 0);

    if(errno != 0){
        /* errno has changed, so error has occurred */

        if(errno == ERANGE){
            /* correct value is outside range of
            ** representable values. Case of overflow
            ** error
            */

            if((retval == LONG_MAX) || (retval == LONG_MIN)){
                /* Error case. Handle accordingly. */
            }else if(errno == EINVAL){
                /* The value of base is not supported */
                /* Handle appropriately */
            }
        }
    }
    /* retval contains the long integer. */
}

```

The following example uses the **wcstoul** subroutine to convert a wide character string to an unsigned long integer:

```

#include <stdlib.h>
#include <locale.h>
#include <errno.h>

extern int errno;

main()
{
    wchar_t  *pwcs, *endptr;
    unsigned long int  retval;

    (void)setlocale(LC_ALL, "");

    /*
    ** Let pwcs point to a wide character null terminated
    ** string containing an unsigned long integer value.
    */
    errno = 0; /* set errno to zero */
    retval = wcstoul(pwcs, &endptr, 0);

    if(errno != 0){
        /* error has occurred */
        if(retval == ULONG_MAX || errno == ERANGE){
            /*
            ** Correct value is outside of
            ** representable value. Handle appropriately
            */
        }else if(errno == EINVAL){
            /* The value of base is not representable */
            /* Handle appropriately */
        }
    }
}

```

```

    }
}
/* retval contains the unsigned long integer. */
}

```

Wide character string copy subroutines

The following multicultural support subroutines copy wide character strings:

Subroutine	Description
wscpy	Copies a wide character string to another wide character string.
wcsncpy	Copies a specific number of characters from a wide character string to another wide character string.
wscat	Appends a wide character string to another wide character string.
wcsncat	Appends a specific number of characters from a wide character string to another wide character string.

Example:

The following example uses the **wscpy** subroutine to copy a wide character string into a wide character array:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2;
    size_t n;

    (void)setlocale(LC_ALL, "");
    /*
    ** Allocate the required wide character array.
    */
    pwcs1 = (wchar_t *)malloc( (wcslen(pwcs2) +1)*sizeof(wchar_t));
    wscpy(pwcs1, pwcs2);
    /*
    ** pwcs1 contains a copy of the wide character string in pwcs2
    */
}

```

Wide character string search subroutines

The following multicultural support subroutines are used to search for wide character strings:

Subroutine	Description
wcschr	Searches for the first occurrence of a wide character in a wide character string.
wcsrchr	Searches for the last occurrence of a wide character in a wide character string.
wcspbrk	Searches for the first occurrence of several wide characters in a wide character string.
wcsspn	Determines the number of wide characters in the initial segment of a wide character string.
wcscspn	Searches for a wide character string.
wcswcs	Searches for the first occurrence of a wide character string within another wide character string.
wcstok	Breaks a wide character string into a sequence of separate wide character strings.

Examples:

The following example uses the **wcschr** subroutine to locate the first occurrence of a wide character in a wide character string:

```
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, wc, *pws;
    int     retval;

    (void)setlocale(LC_ALL, "");

    /*
    ** Let pwcs1 point to a wide character null terminated string.
    ** Let wc point to the wide character to search for.
    **
    */
    pws = wcschr(pwcs1, wc);
    if (pws == (wchar_t )NULL ){
        /* wc does not occur in pwcs1 */
    }else{
        /* pws points to the location where wc is found */
    }
}
```

The following example uses the **wcsrchr** subroutine to locate the last occurrence of a wide character in a wide character string:

```
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, wc, *pws;
    int     retval;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs1 point to a wide character null terminated string.
    ** Let wc point to the wide character to search for.
    **
    */
    pws = wcsrchr(pwcs1, wc);
    if (pws == (wchar_t )NULL ){
        /* wc does not occur in pwcs1 */
    }else{
        /* pws points to the location where wc is found */
    }
}
```

The following example uses the **wcspbrk** subroutine to locate the first occurrence of several wide characters in a wide character string:

```
#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2, *pws;

    (void)setlocale(LC_ALL, "");

    /*
```

```

** Let pwcs1 point to a wide character null terminated string.
** Let pwcs2 be initialized to the wide character string
** that contains wide characters to search for.
*/
pws = wcsprk(pwcs1, pwcs2);

if (pws == (wchar_t) NULL){
    /* No wide character from pwcs2 is found in pwcs1 */
}else{
    /* pws points to the location where a match is found */
}
}

```

The following example uses the **wcsspn** subroutine to determine the number of wide characters in the initial segment of a wide character string segment:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2;
    size_t count;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs1 point to a wide character null terminated string.
    ** Let pwcs2 be initialized to the wide character string
    ** that contains wide characters to search for.
    */
    count = wcsspn(pwcs1, pwcs2);
    /*
    ** count contains the length of the segment.
    */
}

```

The following example uses the **wcscspn** subroutine to determine the number of wide characters not in a wide character string segment:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2;
    size_t count;

    (void)setlocale(LC_ALL, "");

    /*
    ** Let pwcs1 point to a wide character null terminated string.
    ** Let pwcs2 be initialized to the wide character string
    ** that contains wide characters to search for.
    */
    count = wcscspn(pwcs1, pwcs2);
    /*
    ** count contains the length of the segment consisting
    ** of characters not in pwcs2.
    */
}

```

The following example uses the **wcswcs** subroutine to locate the first occurrence of a wide character string within another wide character string:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1, *pwcs2, *pws;

    (void)setlocale(LC_ALL, "");
    /*
    ** Let pwcs1 point to a wide character null terminated string.
    ** Let pwcs2 be initialized to the wide character string
    ** that contains wide characters sequence to locate.
    */
    pws = wcs wcs(pwcs1, pwcs2);
    if (pws == (wchar_t)NULL){
        /* wide character sequence pwcs2 is not found in pwcs1 */
    }else{
        /*
        ** pws points to the first occurrence of the sequence
        ** specified by pwcs2 in pwcs1.
        */
    }
}

```

The following example uses the `wcstok` subroutine to tokenize a wide character string:

```

#include <string.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wchar_t *pwcs1 = L"?a???b,.,#c";
    wchar_t *pwcs;

    (void)setlocale(LC_ALL, "");
    pwcs = wcstok(pwcs1, L"?");
    /* pwcs points to the token: L"a" */
    pwcs = wcstok((wchar_t *)NULL, L",");
    /* pwcs points to the token: L"??b" */
    pwcs = wcstok((wchar_t *)NULL, L"#");
    /* pwcs points to the token: L"c" */
}

```

Wide character input/output subroutines

Multicultural support provides subroutines for both formatted and unformatted I/O.

Formatted wide character I/O:

The `printf` and `scanf` subroutines allow for the formatting of wide characters. The `printf` and `scanf` subroutines have two additional format specifiers for wide character handling: `%C` and `%S`. The `%C` and `%S` format specifiers allow I/O on a wide character and a wide character string, respectively. They are similar to the `%c` and `%s` format specifiers, which allow I/O on a multibyte character and string.

The multibyte subroutines accept a multibyte array and output a multibyte array. To convert multibyte output from a multibyte subroutine to a wide character string, use the `mbstowcs` subroutine.

Unformatted wide character I/O:

Unformatted wide character I/O subroutines are used when a program requires code set-independent I/O for characters from multibyte code sets. For example, use the `fgetwc` or `getwc` subroutine to input a multibyte character. If the program uses the `getc` subroutine to input a multibyte character, the program must call the `getc` subroutine once for each byte in the multibyte character.

Wide character input subroutines read multibyte characters from a stream and convert them to wide characters. The conversion is done as if the subroutines call the **mbtowc** and **mbstowcs** subroutines.

Wide character output subroutines convert wide characters to multibyte characters and write the result to the stream. The conversion is done as if the subroutines call the **wctomb** and **wcstombs** subroutines.

The **LC_CTYPE** category of the current locale affects the behavior of wide character I/O subroutines.

Reading and processing an entire file:

If a program must go through an entire file that must be handled in wide character code form, use one of the following ways:

- In the case of multibyte characters, use either the **read** or **fread** subroutine to convert a block of text data into a buffer. Convert one character at a time in this buffer using the **mbtowc** subroutine. Handle special cases of multibyte characters crossing block boundaries. For multibyte code sets, do not use the **mbstowcs** subroutine on this buffer. On an invalid or a partial multibyte character sequence, the **mbstowcs** subroutine returns -1 without indicating how far it successfully converted the data. You can use the **mbstowcs** subroutine with single-byte code sets because you will not run into a partial-byte sequence problem with single-byte code sets.
- Use the **fgetws** subroutine to obtain a line from the file. If the returned wide character string contains a wide character <new-line>, then a complete line is obtained. If there is no <new-line> wide character, the line is longer than expected, and more calls to the **fgetws** subroutine are needed to obtain the complete line. If the program can efficiently process one line at a time, this approach is recommended.
- If the **fgets** subroutine is used to read a multibyte file to obtain one line at a time, a split multibyte character may result. Handle this condition just as in the case of the **read** subroutine breaking up a multibyte character across successive reads. If you can guarantee that the input line length is not more than a set limit, a buffer of that size (plus 1 for null) can be used, thereby avoiding the possibility of a split multibyte character. If the program can efficiently process one line at a time, this approach may be used. Because of the possibility of split bytes in the buffer, use the **fgetws** subroutine in preference to the **fgets** subroutine for multibyte characters.
- Use the **fgetwc** subroutine on the file to read one wide character code at a time. If a file is large, the function call overhead becomes large and reduces the value of this method.

The decision of which of these methods to use should be made on a per program basis. The **fgetsw** subroutine option is recommended, as it is capable of optimum performance and the program does not have to handle the special cases.

Input subroutines:

The **wint_t** data type is required to represent the wide character code value as well as the end-of-file (EOF) marker. For example, consider the case of the **fgetwc** subroutine, which returns a wide character code value:

**Subroutine return value
declaration**

wchar_t fgetwc();

Description

If the **wchar_t** data type is defined as a **char** value, the y-umlaut symbol cannot be distinguished from the end-of-file (EOF) marker in the ISO8859-1 code set. The 0xFF code point is a valid character (y umlaut). Hence, the return value cannot be the **wchar_t** data type. A data type is needed that can hold both the EOF marker and all the code points in a code set.

int fgetwc();

On some machines, the **int** data type is defined to be 16 bits. When the **wchar_t** data type is larger than 16 bits, the **int** value cannot represent all the return values.

The **wint_t** data type is therefore needed to represent the **fgetwc** subroutine return value. The **wint_t** data type is defined in the **wchar.h** file.

Subroutine return value	Description
<code>fgetc</code>	Gets next wide character from a stream.
<code>fgetcws</code>	Gets a string of wide characters from a stream.
<code>getc</code>	Gets next wide character from a stream.
<code>getwchar</code>	Gets next wide character from standard input.
<code>getws</code>	Gets a string of wide characters from a standard input.
<code>ungetc</code>	Pushes a wide character onto a stream.

Output subroutines:

The following subroutines are used for wide character output:

Subroutine	Description
<code>fputc</code>	Writes a wide character to an output stream.
<code>fputcws</code>	Writes a wide character string to an output stream.
<code>putc</code>	Writes a wide character to an output stream.
<code>putwchar</code>	Writes a wide character to standard output.
<code>putws</code>	Writes a wide character string to standard output.

Examples:

The following example uses the `fgetc` subroutine to read wide character codes from a file:

```
#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wint_t  retval;
    FILE    *fp;
    wchar_t *pwcs;

    (void)setlocale(LC_ALL, "");

    /*
    ** Open a stream.
    */
    fp = fopen("file", "r");

    /*
    ** Error Handling if fopen was not successful.
    */
    if(fp == NULL){
        /* Error handler */
    }else{
        /*
        ** pwcs points to a wide character buffer of BUFSIZ.
        */
        while((retval = fgetc(fp)) != WEOF){
            *pwcs++ = (wchar_t)retval;
            /* break when buffer is full */
        }
    }
    /* Process the wide characters in the buffer */
}
```

The following example uses the `getwchar` subroutine to read wide characters from standard input:

```
#include <stdio.h>
#include <locale.h>
#include <stdlib.h>
```

```

main()
{
    wint_t  retval;
    FILE    *fp;
    wchar_t *pwcs;

    (void)setlocale(LC_ALL, "");

    index = 0;
    while((retval = getwchar()) != WEOF){
        /* pwcs points to a wide character buffer of BUFSIZ. */
        *pwcs++ = (wchar_t)retval;
        /* break on buffer full */
    }
    /* Process the wide characters in the buffer */
}

```

The following example uses the **ungetwc** subroutine to push a wide character onto an input stream:

```

#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    wint_t  retval;
    FILE    *fp;

    (void)setlocale(LC_ALL, "");
    /*
    ** Open a stream.
    */
    fp = fopen("file", "r");

    /*
    ** Error Handling if fopen was not successful.
    */
    if(fp == NULL){
        /* Error handler */
    }
    else{
        retval = fgetwc(fp);
        if(retval != WEOF){
            /*
            ** Peek at the character and return it to the stream.
            */
            retval = ungetwc(retval, fp);
            if(retval == EOF){
                /* Error on ungetwc */
            }
        }
    }
}

```

The following example uses the **fgetws** subroutine to read a file, one line at a time:

```

#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    FILE    *fp;
    wchar_t *pwcs;

    (void)setlocale(LC_ALL, "");

```

```

/*
** Open a stream.
*/
fp = fopen("file", "r");

/*
** Error Handling if fopen was not successful.
*/
if(fp == NULL){
    /* Error handler */
}else{
    /* pwcs points to wide character buffer of BUFSIZ. */
    while(fgetws(pwcs, BUFSIZ, fp) != (wchar_t *)NULL){
        /*
        ** pwcs contains wide characters with null
        ** termination.
        */
    }
}
}

```

The following example uses the **fputwc** subroutine to write wide characters to an output stream:

```

#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    int    index, len;
    wint_t retval;
    FILE   *fp;
    wchar_t *pwcs;

    (void)setlocale(LC_ALL, "");

    /*
    ** Open a stream.
    */
    fp = fopen("file", "w");

    /*
    ** Error Handling if fopen was not successful.
    */
    if(fp == NULL){
        /* Error handler */
    }else{
        /* Let len indicate number of wide chars to output.
        ** pwcs points to a wide character buffer of BUFSIZ.
        */
        for(index=0; index < len; index++){
            retval = fputwc(*pwcs++, fp);
            if(retval == WEOF)
                break; /* write error occurred */
                /* errno is set to indicate the error. */
        }
    }
}

```

The following example uses the **fputws** subroutine to write a wide character string to a file:

```

#include <stdio.h>
#include <locale.h>
#include <stdlib.h>

main()
{
    int    retval;

```

```

FILE    *fp;
wchar_t *pwcs;

(void)setlocale(LC_ALL, "");

/*
** Open a stream.
*/
fp = fopen("file", "w");

/*
** Error Handling if fopen was not successful.
*/
if(fp == NULL){
    /* Error handler */

}else{
    /*
    ** pwcs points to a wide character string
    ** to output to fp.
    */
    retval = fputws(pwcs, fp);
    if(retval == -1){
        /* Write error occurred          */
        /* errno is set to indicate the error */
    }
}
}

```

Working with the wide character constant

Use the **L** constant for ASCII characters only. For ASCII characters, the **L** constant value is numerically the same as the code point value of the character. For example, **L'a** is same as **a**. The **L** constant obtains the **wchar_t** value of an ASCII character for assignment purposes. A wide character constant is introduced by the **L** specifier. For example:

```
wchar_t wc = L'x' ;
```

A wide character code corresponding to the character **x** is stored in **wc**. The C compiler converts the character **x** using the **mbtowc** or **mbstowcs** subroutine as appropriate. This conversion to wide characters is based on the current locale setting at compile time. Because ASCII characters are part of all supported code sets and the wide character representation of all ASCII characters is the same in all locales, **L'x'** results in the same value across all code sets. However, if the character **x** is non-ASCII, the program may not work when it is run on a different code set than used at compile time. This limitation impacts some programs that use switch statements using the wide character constant representation.

wchar.h header file

The **wchar.h** header file declares information that is necessary for programming with multibyte and wide character subroutines. The **wchar.h** header file declares the **wchar_t**, **wctype_t**, and **wint_t** data types, as well as several functions for testing wide characters. Because the number of characters implemented as wide characters exceeds that of basic characters, it is not possible to classify all wide characters into the existing classes used for basic characters. Therefore, it is necessary to provide a way of defining additional classes specific to some locale. The action of these subroutines is affected by the current locale.

The **wchar.h** header file also declares subroutines for manipulating wide character strings (that is, **wchar_t** data type arrays). Array length is always determined in terms of the number of **wchar_t** elements in an array. A null wide character code ends an array. A pointer to a **wchar_t** data type array or void array always points to the initial element of the array.

Note: If the number of **wchar_t** elements in an array exceeds the defined array length, unpredictable results can occur.

Globalized regular expression subroutines

Programs that contain globalized regular expressions can use the **regcomp**, **regex**, **regerror**, **regfree**, and **fnmatch** subroutines.

The following subroutines are available for use with globalized regular expressions.

regcomp

Compiles a specified basic or extended regular expression into an executable string.

regex

Compares a null-terminated string with a compiled basic or extended regular expression that must have been previously compiled by a call to the **regcomp** subroutine.

regerror

Provides a mapping from error codes returned by the **regcomp** and **regex** subroutines to printable strings.

regfree

Frees any memory allocated by the **regcomp** subroutine associated with the compiled basic or extended regular expression. The expression is no longer treated as a compiled basic or extended regular expression after it is given to the **regfree** subroutine.

fnmatch

Checks a specified string to see if it matches a specified pattern. You can use the **fnmatch** subroutine in an application that reads a dictionary to find which entries match a given pattern. You also can use the **fnmatch** subroutine to match path names to patterns.

Examples

The following example compiles a globalized regular expression and matches a string using this compiled expression. A match is found for the first pattern, but no match is found for the second pattern.

```
#include <locale.h>
#include <regex.h>

#define BUFSIZE 256

main()
{
    char *p;

    char *pattern[] = {
        "hello[0-9]*",
        "1234"
    };

    char *string = "this is a test string hello112 and this is test";
    /* This is the source string for matching */

    int retval;
    regex_t re;
    char buf[BUFSIZE];

    int i;

    setlocale(LC_ALL, "");

    for(i = 0; i < 2; i++){
        retval = match(string, pattern[i], &re);
        if(retval == 0){
            printf("Match found \n");
        }else{
            regerror(retval, &re, buf, BUFSIZE);
        }
    }
}
```

```

                printf("error = %s\n", buf);
            }
        }
    regfree( &re);
}

int match(char *string, char *pattern, regex_t *re)
{
    int    status;

    if((status=regcomp( re, pattern, REG_EXTENDED))!= 0)
        return(status);
    status = regexec( re, string, 0, NULL, 0);
    return(status);
}

```

The following example finds all substrings in a line that match a pattern. The numbers 11 and 2001 are matched. Every digit that is matched counts as one match. There are six such matches corresponding to the six digits supplied in the string.

```

#include      <locale.h>
#include      <regex.h>

#define      BUFSIZE  256

main()
{
    char    *p;

    char    *pattern = "[0-9]";
    char    *string = "Today is 11 Feb 2001 ";

    int     retval;
    regex_t re;
    char    buf[BUFSIZE];
    regmatch_t pmatch[100];
    int     status;
    char    *ps;

    int     eflag;

    setlocale(LC_ALL, "");

    /* Compile the pattern */

    if((status = regcomp( &re, pattern, REG_EXTENDED))!= 0){
        regerror(status, &re, buf, 120);
        exit(2);
    }

    ps = string;
    printf("String to match=%s\n", ps);
    eflag = 0;

    /* extract all the matches */
    while( status = regexec( &re, ps, 1, pmatch, eflag)== 0){
        printf("match found at: %d, string=%s\n",
            pmatch[0].rm_so, ps +pmatch[0].rm_so);
        ps += pmatch[0].rm_eo;
        printf("\nNEXTString to match=%s\n", ps);
        eflag = REG_NOTBOL;
    }
    regfree( &re);
}

```

The following example uses the `fnmatch` subroutine to read a directory and match file names with a pattern.

```
#include          <locale.h>
#include          <fnmatch.h>
#include          <sys/dir.h>

main(int argc, char *argv[] )
{
    char    *pattern;
    DIR     *dir;
    struct dirent    *entry;
    int     ret;

    setlocale(LC_ALL, "");

    dir = opendir(".");

    pattern = argv[1];

    if(dir != NULL){
        while( (entry = readdir(dir)) != NULL){
            ret = fnmatch(pattern, entry->d_name,
                FNM_PATHNAME|FNM_PERIOD);
            if(ret == 0){
                printf("%s\n", entry->d_name);
            }else if(ret == FNM_NOMATCH){
                continue ;
            }else{
                printf("error file=%s\n",
                    entry->d_name);
            }
        }
        closedir(dir);
    }
}
```

Code sets for multicultural support

The globalization of AIX is based on the assumption that all code sets can be divided into any number of character sets.

To understand code sets, it is necessary to first understand character sets. A *character set* is a collection of predefined characters based on the specific needs of one or more languages without regard to the encoding values used to represent the characters. The choice of which code set to use depends on the user's data processing requirements. A particular character set can be encoded using different encoding schemes. For example, the ASCII character set defines the set of characters found in the English language. The Japanese Industrial Standard (JIS) character set defines the set of characters used in the Japanese language. Both the English and Japanese character sets can be encoded using different code sets.

A *code page* is similar to a code set with the limitation that a code page specification is based on a 16-column by 16-row matrix. The intersection of each column and row defines a coded character.

Consider the following when working with code sets:

- Do not assume the size of all characters to be 8 bits, or 1 byte. Characters may be 1, 2, 3, 4 or more bytes.
- Do not assume the encoding of any code set.
- Do not hard code names of code sets, locales, or fonts because it can impact portability.

The following code sets are supported:

- Support for industry-standard code sets is provided. The **ISO8859** family of code sets provides a range of single-byte code set support that includes:
 - Latin-1
 - Latin-2
 - Latin-4
 - Cyrillic
 - Arabic
 - Greek
 - Hebrew
 - Turkish

The following industry-standard code sets are available:

- The IBM-eucJP code set is the industry-standard code set used to support the Japanese locale.
- The IBM-eucKR code set is the industry-standard code set used to support Korean countries.
- The IBM-eucTW code set is the industry-standard code set used to support Traditional Chinese countries.
- The IBM-eucCN code set is the industry-standard code set used to support countries using Simplified Chinese.
- The UTF-8 code set is a Universal Transformation Format of Unicode/ISO10646 used to support multiple languages at once (including Simplified Chinese, Traditional Chinese, and Chinese characters used in Japanese and Korean).
- **ISO8859-15** standard code set is a replacement standard for the existing ISO8859-1 code set that is currently in use by the western European locales, the United States, and Canada. The need for another code set resulted from the introduction of the euro currency unit and the need for European countries to be able to do business transactions using the euro. In addition, ISO8859-15 contains 7 additional characters for the French and Finnish languages.
- Support is also provided for the personal computer (PC) based code sets **IBM-856**, **IBM-943**, **IBM-932**, and **IBM-1046**. IBM-856 is a single-byte code set used to support Hebrew countries. IBM-943 and IBM-932 are multibyte code set used to support the Japanese locale. IBM-1046 is a single-byte code set used to support Arabic countries.
- **IBM-1129** is a single-byte code set used to support Vietnamese.
- **TIS-620** is a single-byte code set used to support Thai.
- **IBM-1124** is a single-byte code set used to support Ukrainian.
-
- Full Unicode support is provided by the **UTF-8** code set for *all* languages and territories supported by AIX. The UTF-8 code set is a Universal Transformation Format of Unicode/ISO10646 used to support multiple languages at once. The UTF-8 code set provides the most complete solution for use in environments where multiple languages and alphabets must be processed. The Unicode/UTF-8 code set also provides full support for the common European currency (euro).
- **IBM-1252** code set support is provided as a compatibility option for users who require a single byte code set environment containing the euro currency symbol. The structure of the IBM-1252 code set is identical to the industry-standard code set ISO8859-1, except that additional graphic characters are added in the ISO control character range from 0x80 through 0x9F. The euro currency symbol is located at hexadecimal valTXx80 in the IBM-1252 code set.

Related concepts:

“ASCII characters” on page 51

ASCII is a code set containing 128 code points (0x00 through 0x7F). The ASCII character set contains control characters, punctuation marks, digits, and the uppercase and lowercase English alphabet. Several 8-bit code sets incorporate ASCII as a proper subset. However, throughout this document, ASCII refers to 7-bit-only code sets. To emphasize this, it is referred to as 7-bit ASCII. The 7-bit ASCII code set is a proper subset of all supported code sets and is referred to as the *portable character set*.

“List of converters” on page 88

Converters change data from one code set to another. The sets of converters supported with the iconv library are listed in the following sections.

Single-byte and multibyte code sets

A single-byte encoding method is sufficient for representing the English character set because the number of characters is not large. To support larger alphabets, such as Japanese and Chinese, additional code sets containing multibyte encodings are necessary. All supported single-byte and multibyte code sets contain the single-byte ASCII character set. Therefore, programs that handle multibyte code sets must handle character encodings of one or more bytes.

An example of a single-byte code set is the ISO 8859 family of code sets. Examples of multibyte character sets are the IBM-eucJP and the IBM-943 code sets. The single-byte code sets have at most 256 characters and the multibyte code sets have more than 256 (without any theoretical limit).

Unique code-point range

None of the supported code sets have bytes 0x00 through 0x3F in any byte of a multibyte character. This group of code points is called the *unique code-point range*.

These code points always refer to the same characters as specified for 7-bit ASCII. This is a special property governing all supported code sets. ASCII Characters in the Unique Code-Point Range (“ASCII characters” on page 51) lists the characters in the unique code-point range.

Data representation

Because the encoding for some characters requires more than one byte, a single character may be represented by one or several bytes when data is created in files or transferred between a computer and its I/O devices. This external representation of data is referred to as the file code or *multibyte character code* representation of a character.

For processing strings of such characters, it is more efficient to convert file codes into a uniform representation. This converted form is intended for internal processing of characters. This internal representation of data is referred to as the *process code* or *wide character code* representation of the character. An understanding of multibyte character and wide character codes is essential to the overall globalization strategy.

Multibyte character code data representation

A multibyte character code is an external representation of data, regardless of whether it is character input from a keyboard or a file on a disk. Within the same code set, the number of bytes that represent the multibyte code of a character can vary. You must use multicultural support functions for character processing to ensure code set independence.

For example, a code set may specify the following character encodings:

```
C = 0x43
* = 0x81 0x43
*C = 0x81 0x43& 0x43
```

A program searching for C, not accounting for multibyte characters, finds the second byte of the *C string and assumes it found C when in fact it found the second byte of the * (asterisk) character.

Wide character data representation

The wide character code was developed so that multibyte characters could be processed more efficiently internally in the system. A multibyte character representation is converted into a uniform internal representation (wide character code) so that internally all characters have the same length. Using this internal form, character processing can be done in a code set-independent fashion. The wide character code refers to this internal representation of characters.

The **wchar_t** data type is used to represent the wide character code of a character. The size of the **wchar_t** data type is implementation-specific. It is a **typedef** definition and can be found in the **ctype.h**, **stddef.h**, and **stdlib.h** files. No program should assume a particular size for the **wchar_t** data type, enabling programs to run under implementations that use different sizes for the **wchar_t** data type.

On AIX 4.3, the **wchar_t** datatype is implemented as an unsigned short value (16 bits). On AIX 5.1 and later, the **wchar_t** datatype is 32-bit in the 64-bit environment and 16-bit in the 32-bit environment. . The locale methods have been standardized such that in most locales, the value stored in the **wchar_t** for a particular character will always be its Unicode data value. For applications which are intended to run only on AIX, this allows certain applications handle the **wchar_t** datatype in a consistent fashion, even if the underlying code set is unknown. All locales use Unicode for their wide character code values (process code), except the IBM-eucTW code set. The IBM-eucTW code set (LANG =**zh_TW**) contains many characters that are not contained in the Unicode standard. Because of this, it is impossible to represent these characters with a Unicode wide character value. Applications that need to have Unicode based **wchar_t** data for Traditional Chinese should use the **Zh_TW** locale (big5 code set) instead.

Do not assume that the **char** data type is either signed or unsigned. This is platform-specific. If the particular system that is used defines **char** to be **signed**, comparisons with full 8-bit quantity will yield incorrect results. As all the 8-bits are used in encoding a character, be sure to declare **char** as **unsigned char** wherever necessary. Also, note that if a **signed char** value is used to index an array, it may yield incorrect results. To make programs portable, define 8-bit characters as **unsigned char**.

Character properties

Every character has several language-dependent attributes or properties. These properties are called *class properties*. For example, the lowercase letter a in U.S. English has the following properties:

- alphabetic
- hexadecimal digit
- printable
- lowercase
- graphic

Character class properties are specified by the **LC_CTYPE** category.

Collation-Order properties

Character ordering or collation refers to the culture-specific ordering of characters. This ordering differs from that based on the ordinal value of a character in a code set.

Character ordering or *collation* refers to the culture-specific ordering of characters. This ordering differs from that based on the ordinal value of a character in a code set. Collation-based ordering is dependent on the language. Character collation is specified by the **LC_COLLATE** category. The term *collating element* refers to one or more characters that have a collation value in a specific locale. The Spanish ll character is an example of a multicharacter collating element.

To sort the characters in any given language in the proper order, a weight is assigned to each character so that the characters sort as expected. However, a character's sort value and code-point value are not necessarily related.

One set of weights is not sufficient to sort strings for all languages. For example, in the case of the German words `b<a-umlaut>ch` and `bane`, if there is only one set of weights, and the weight of the letter `a` is less than that of `<a-umlaut>`, then `bane` sorts before `b<a-umlaut>ch`. However, the opposite result is correct. To satisfy the requirement of this example, two sets of weights, the Primary and Secondary Weights, are given to each character in the language. In the case of the characters `a` and `<a-umlaut>`, they have the same Primary Weights, but differ in their Secondary Weights. In the German locale, the Secondary Weight of `a` is less than that of `<a-umlaut>`.

The sorting algorithm first compares the two strings based on the Primary Weights of each character. If the Primary Weight values are the same, the two strings are compared again based on their Secondary Weights. In this example, the Primary Weights of the first two characters `ba` and `b<a-umlaut>` are the same, but the Primary Weights of the characters that follow (`c` and `n`, respectively) differ. As a result of this comparison, `b<a-umlaut>ch` is sorted before `bane`.

Here, the Secondary Weights are not used to collate the strings. However, as in the case of the strings `bach` and `b<a-umlaut>ch`, Secondary Weights must be used to get the proper order. When compared using Primary Weight values, these two strings are found to be equivalent. To break the tie, the Secondary Weights of `a` and `<a-umlaut>` are used. Because the Secondary Weight of `a` is less than that of `<a-umlaut>`, the string `bach` sorts before `b<a-umlaut>ch`.

Characters having the same Primary Weights belong to the same *equivalence class*. In this example, the characters `a` and `<a-umlaut>` are said to be members of the same equivalence class.

In string collation, each pair of strings is first compared based on Primary Weight. If the two strings are equal, they are compared again based on their Secondary Weights. If still equal, they are compared again based on Tertiary Weights up to the limit set by the `COLL_WEIGHTS_MAX` collating weight limit specified in the `sys/limits.h` file.

Code set width

Code set width refers to the maximum number of bytes required to represent a character as a file code. This information is specified by the `LC_CTYPE` category.

Code set display width

Code set display width refers to the maximum number of columns required to display a character on a terminal. This information is specified by the `LC_CTYPE` category.

ASCII characters

ASCII is a code set containing 128 code points (0x00 through 0x7F). The ASCII character set contains control characters, punctuation marks, digits, and the uppercase and lowercase English alphabet. Several 8-bit code sets incorporate ASCII as a proper subset. However, throughout this document, ASCII refers to 7-bit-only code sets. To emphasize this, it is referred to as 7-bit ASCII. The 7-bit ASCII code set is a proper subset of all supported code sets and is referred to as the *portable character set*.

underscore	5F	_	del	7F	

Code set strategy

Each locale in the system defines which code set it uses and how the characters within the code set are manipulated. Because multiple locales can be installed on the system, multiple code sets can be used by different users on the system. While the system can be configured with locales using different code sets, all system utilities assume that the system is running under a single code set.

Most commands have no knowledge of the underlying code set being used by the locale. The knowledge of code sets is hidden by the code set-independent library subroutines (globalization library), which pass information to the code set-dependent subroutines.

Because many programs rely on ASCII, all code sets include the 7-bit ASCII code set as a proper subset. Because the 7-bit ASCII code set is common to all supported code sets, its characters are sometimes

referred to as the *portable character set*. The 7-bit ASCII code set is based on the ISO646 definition and contains the control characters, punctuation characters, digits (0-9), and the English alphabet in uppercase and lowercase.

Code set structure

Each code set is divided into the following principal areas:

- Graphic Left (GL): Columns 0-7
- Graphic Right (GR): Columns 8-F

The first two columns of each code set are reserved by International Organization for Standardization (ISO) standards for control characters. The terms C0 and C1 are used to denote the control characters for the Graphic Left and Graphic Right areas, respectively.

Note: The IBM PC code sets use the C1 control area to encode graphic characters.

The remaining six columns are used to encode graphic characters. Graphic characters are considered to be printable characters, while the control characters are used by devices and applications to indicate some special function.

Control characters

Name	Value	Description
NUL	00	Null
SOH	01	Start of header
STX	02	Start of text
ETX	03	End of text
EOT	04	End of transmission
ENQ	05	Enquiry
ACK	06	Acknowledge
BEL	07	Bell
BS	08	Backspace
HT	09	Horizontal tab
LF	0A	Line feed
VT	0B	Vertical tab
FF	0C	Form feed
CR	0D	Carrier return
SO	0E	Shift Out
SI	0F	Shift In
DLE	10	Data link escape
DC1	11	Device control 1
DC2	12	Device control 2
DC3	13	Device control 3
DC4	14	Device control 4
NAK	15	Not acknowledge
SYN	16	Synchronous idle
ETB	17	End of transmission block
CAN	18	Cancel
EM	1	End of media
SUB	1A	Substitute character
ESC	1B	Escape character

Name	Value	Description
IS4	1C	Info Separator Four
IS3	1D	Info Separator Three
IS2	1E	Info Separator Two
IS1	1F	Info Separator One

Graphic characters

Each code set can be considered to be divided into one or more character sets, with each character having a unique coded value. The ISO standard reserves six columns for encoding characters and does not allow graphic characters to be encoded in the control character columns.

Single-byte and multibyte code sets

Code sets that use all 8 bits of a byte can support European, Middle Eastern, and other alphabetic languages. Such code sets are called single-byte code sets. Single-byte code sets have a limit of encoding 191 characters, not including control characters.

Languages that require more than 191 characters use a mixture of single-byte characters (8 bits) and multibyte characters (more than 8 bits). The system can support any number of bits to encode a character.

ISO code sets

The code sets listed in the following topics are based on definitions set by the International Organization for Standardization (ISO).

ISO646-IRV

The **ISO646-IRV code set** below defines the code set used for information processing based on a 7-bit encoding. The character set associated with this code set is derived from the ASCII characters.

		First Hexadecimal Digit															
		0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
Second Hexadecimal Digit	0	NUL	DLE	BLANK (SPACE)	0	@	P	·	p								
	1	SOH	DC1	!	1	A	Q	a	q								
	2	STX	DC2	°	2	B	R	b	r								
	3	ETX	DC3	#	3	C	S	c	s

ISO8859 family

ISO8859 is a family of single-byte encodings based on and compatible with other ISO, American National Standards Institute (ANSI), and European Computer Manufacturer's Association (ECMA) code extension techniques. The ISO8859 encoding defines a family of code sets with each member containing its own unique character sets. The 7-bit ASCII code set is a proper subset of each of the code sets in the ISO8859 family.

While the ASCII code set defines an order for the English alphabet, the Graphic Right (GR) characters are not ordered according to any specific language. The locale defines the language-specific ordering.

Each code set includes the ASCII character set plus its own unique character set. The ISO8859 encoding figure shows the ISO8859 general encoding scheme.

Character Encoding	Code Point	Description	Count
000xxxxx	00-1F	Controls	32
00100000	20	Space	1
0xxxxxxx	21-7E	7-bit	94
01111111	7F	Delete	1
100xxxxx	80-9F	Controls	32
10100000	A0	No-break Space	1
1xxxxxxx	A1-F	8-bit	96

Code set ISO8859-1

The available symbols and the layout of code set ISO8859-1 are covered in this section.

The following figure summarizes the available symbols and shows the layout of Code Set ISO8859-1. For a textual representation of this code set, see “ISO8859-1” on page 185.

		First Hexadecimal Digit

Extended UNIX code (EUC) encoding scheme

The EUC encoding scheme defines a set of encoding rules that can support one to four character sets. The encoding rules are based on the ISO2022 definition for the encoding of 7-bit and 8-bit data. The EUC encoding scheme uses control characters to identify some of the character sets. The following table shows the basic structure of all EUC encoding.

EUC	Character Encoding
CS0	0xxxxxxx
CS1	1xxxxxxx 1xxxxxxx 1xxxxxxx 1xxxxxxx 1xxxxxxx 1xxxxxxx ...
CS2	10001110 1xxxxxxx 10001110 1xxxxxxx 1xxxxxxx 10001110 1xxxxxxx 1xxxxxxx 1xxxxxxx ...
CS3	10001111 1xxxxxxx 10001111 1xxxxxxx 1xxxxxxx 10001111 1xxxxxxx 1xxxxxxx 1xxxxxxx ...

The term *EUC* denotes these general encoding rules. A code set based on EUC conforms to the EUC encoding rules but also identifies the specific character sets associated with the specific instances. For example, IBM-eucJP for Japanese refers to the encoding of the Japanese Industrial Standard characters according to the EUC encoding rules.

The first set (CS0) always contains an ISO646 character set. All of the other sets must have the most significant bit (MSB) set to 1 and can use any number of bytes to encode the characters. In addition, all characters within a set must have the following:

- Same number of bytes to encode all characters
- Same column display width (number of columns on a fixed-width terminal)

All characters in the third set (CS2) are always preceded with the control character SS2 (single-shift 2, 0x8e). Code sets that conform to EUC do not use the SS2 control character other than to identify the third set.

All characters in the fourth set (CS3) are always preceded with the control character SS3 (single-shift 3, 0x8f). Code sets that conform to EUC do not use the SS3 control character other than to identify the fourth set.

IBM-eucJP

The EUC for Japanese is an encoding consisting of single-byte and multibyte characters. The encoding is based on ISO2022, Japanese Industrial Standard (JIS), and EUC definitions.

The IBM-eucJP code set consists of the following character sets:

Character set	Description
JISCII	JISX0201 Graphic Left character set
JISX0201.1976	Katakana/Hiragana Graphic Right character set
JISX0208.1983	Kanji level 1 and 2 character sets
IBM-udcJP	IBM-user definable characters

The IBM-eucJP code set is also capable of supporting the following:

Character set	Description
JISX0212.1990	Supplemental Kanji

The IBM-eucJP code set is encoded as follows:

- CS0 maps JISX0201 Graphic Left characters starting at the 0x00 position.
- CS1 maps the JISX0208 character set starting at the 0xa1a1 position. The positions 0xf5a1 through 0xfefe (940 characters) in CS1 are reserved as primary user-definable character areas.
- CS2 maps the JISX0201 Graphic Right starting at the 0x8ea1 position.
- CS3 is capable of mapping JISX0212 starting at the 0x8fa1a1 position. The positions 0x8ff5a1 through 0x8ffefe in CS3 (940 characters) are reserved as secondary user-definable character areas. The positions 0x8feea1 through 0x8ff4fe in CS3 (658 characters) are reserved for future system use. Therefore, users should not use this area.

IBM-eucCN

The EUC for the Simplified Chinese language is an encoding consisting of characters that contain 1 or 2 bytes. The EUC encoding is based on ISO2022, GB2312 as defined by the People's Republic of China, and multibyte character definitions unique to the manufacturer.

The current GB2312 defines 6,763 Simplified Chinese characters and 682 symbols. The IBM-eucCN is based upon a concept of one plane containing up to 94x94 characters. The encoding values of these characters range from 0xa1a1 to 0xfefe.

The GB2312 is mapped into the CS1 of EUC. Specifically, the IBM-eucCN consists of the following character sets:

Character set	Description
ISO0646-IRV	7-bit ASCII character set, Graphic Left.
GB2312.1980	Contains 7445 characters. It occupies positions 0xa1a1 to 0xfedf (some user-defined characters scattered in 0xa1a1 to 0xfedf).
IBM-udcCN	Scattered in GB. It occupies positions 0xa1a1 to 0xfedf. The actual values are: a2a1 -- a2b0 a1e3 -- a2e4 a1ef -- a2f0 a2fd -- a1fe a4f4 -- a4fe a5f7 -- a5fe a6b9 -- a6c0 a6d9 -- a6fe a7c2 -- a7d0 a7f2 -- a7fe a8bb -- a8c4 a8ea -- a9a3 a9f0 -- affe a7fa -- d7fe f8a1 -- fedf
IBM-sbdCN	Scattered in GB. It occupies positions 0xfee0 to 0xfefe.

GB18030

GBK stands for Guo (national) Biao (Standard) Kuo (Extension). GB18030 expands the national "Industry GB" definition to contain all 20,902 Han Characters defined in Unicode and additional DBCS symbols defined in Big-5 code (Traditional Chinese PC defacto standard). GB18030 defines all DBCS characters and symbols in use in mainland China and in Taiwan.

Locale	Code Set	Description
Zh_CN	GB18030	Simplified Chinese, GB18030 Locale

Code Range	Words	Marks
A1A1-A9FE	846	GB2312, GB12345 (GBK/1)
A840-A9A0	192	Big5, Symbols (GBK/5)
B0A1-F7FE	6768	GB2312 (GBK/2)
8140-A0FE	6080	GB13000 (GBK/3)
AA40-FEA0	8160	GB13000 (GBK/4)
AAA1-AFFE	564	User defined 1
F8A1-FEFE	658	User defined 2
A140-A7A0	672	User defined 3

IBM-eucTW

The EUC for the Traditional Chinese language is an encoding consisting of characters that contain 1, 2 and 4 bytes. The EUC encoding is based on ISO2022, the Chinese National Standard (CNS) as defined by Taiwan, and multibyte character definitions unique to the manufacturer.

The current CNS defines 13,501 Chinese characters and 684 symbols. The IBM-eucTW is based upon a concept of 15 planes, each containing up to 8836 (94x94) characters. The encoding values of these characters range from 0xa1a1 to 0xfefe. Characters have presently been defined for only 4 of the planes, with the other planes being reserved for future expansion.

The 15 planes are mapped into the CS1 and CS2 of EUC, with the CS2 of EUC consisting of 14 planes. Specifically, the IBM-eucTW consists of the following character sets:

Character set	Description
ISO646-IRV	7-bit ASCII character set, Graphic Left.
CNS11643.1986-1	Plane 1, containing 6085 characters (5401+684). This plane uses positions 0ax1a1-0xc2c1 and 0xc4a1-0xfdc1.
CNS11643.1986-2	Plane 2, containing 7650 characters. This plane occupies positions 0x8ea2a1a1-0x8ea2f2c4.
CNS11643.1992-3	Plane 4, containing 7298 characters. This plane occupies positions 0x8ea4a1a1-0x8ea4eedc.
IBM-udcTW	Plane 12, containing 6204 characters. This plane is reserved for the User Defined Characters (udc) areas. It occupies the positions 0x8eaca1a1-0x8ea2f2c4.
IBM-sbdTW	Plane 13, containing 325 characters. This plane is reserved for symbols unique to the manufacturer. It occupies positions 0xead1a1-0x8eada4cb.

Planes 3-11 are expected to occupy positions 0x8ea3xxxx to 0x8eabxxxx. Planes 14-15 are expected to occupy positions 0x8eaexxxx to 0x8eafxxxx.

Big5

The Traditional Chinese big5 locale, **Zh_TW**, code set is the most commonly used code set in the PC field that is used to support countries using Traditional Chinese.

Big5 code set defines 13056 characters and 1004 symbols. It includes 684 symbols in CNS11643.192, as well as 325 symbols unique to IBM.

Locale	Code Set	Description
Zh_TW	Big5 (IBM-950)	Traditional Chinese, Big5 Locale

Code range for Big5 locale:

The code range for the Big5 locale is defined in the following tables:

Plan	Code Range	Description
1	A140H - A3E0H	Symbol and Chinese Control Code
1	A440H - C67EH	Commonly Used Characters
2	C940H - F9D5H	Less Commonly Used Characters
UDF	FA40H - FEFE	User-Defined Characters
	8E40H - A0FEH	User-Defined Characters
	8140H - 8DFEH	User-Defined Characters
	8181H - 8C82H	User-Defined Characters
	F9D6H - F9F1H	User-Defined Characters

Code Set	Words	Code Range	Marks
Commonly Used Area	5841	A140-C67E	
Less Commonly Used Area	7652	C940-F9D5	
ET Unique Area (1)	308	C6A1-C878	
ET Unique Area (2)	7	C8CD-C8D3	
IBM Unique Area	251	F286-F9A0	Low-Byte Range 81-A0
User-Defined Area (1)	785	FA40-FEFE	
User-Defined Area (2)	2983	8E40-A0FE	
User-Defined Area (3)	2041	8140-8DFE	
User-Defined Area (4)	354	8181-8C82	Low-Byte Range 81-AQ
User-Defined Area (5)	41	F9D6-F9FE	

IBM-eucKR

The EUC for the Korean language is an encoding consisting of single-byte and multibyte characters. The encoding is based on ISO2022, Korean Standard Code set, and EUC definitions.

The Korean EUC code set consists of the following main character groups:

- ASCII (English)
- Hangul (Korean characters)

The Hangul code set includes Hangul and Hanja (Chinese) characters. One Hangul character can comprise several consonants and vowels. However, most Hangul words can be expressed in Hanja. Each Hanja character has its own meaning and is more specific than Hangul.

The IBM-eucKR consists of the following character sets:

Character set	Description
ISO646-IRV	7-bit ASCII character set, Graphic Left
KSC5601.1987-0	Korean Graphic Character Set, Graphic Right

IBM PC code sets

IBM PC code sets are the code sets originally supported on the IBM PC systems and AIX. The IBM PC code sets assign graphic characters to the Control One (C1) control area. Applications that depend on these control characters cannot support these code sets.

The ASCII characters are encoded with the most significant bit (MSB) zero in positions 0x20-0x7e. The extended Latin 1, combined with the IBM PC unique character sets, make up the extended set of characters which are encoded in positions 0x80-0xfe. The following table shows the location of the control, ASCII, and extended characters for the IBM-850 code set.

Character Encoding	Code Point	Description	Count
000xxxxx	00–1F	Controls	32
00100000	20	Space	1
0xxxxxxx	21–7E	7-bit	94
01111111	7F	Delete	1
1xxxxxxx	80–FE	8-bit	17
11111111	FF	All ones	1

The IBM PC unique character set includes the following:

Table 4. IBM PC Unique Character Set

Symbol	Return Code
Florin sign	0x9f
Quarter-hashed	0xb0
Half-hashed	0xb1
Full-hashed	0xb2
Vertical bar	0xb3
Right-side middle	0xb4
Double right-side middle	0xb9
Double vertical bar	0xba
Double upper right-corner box	0xbb
Double lower right-corner box	0xbc
Upper right-corner box	0xbf

Table 4. IBM PC Unique Character Set (continued)

Symbol	Return Code
Lower left-corner box	0xc0
Bottom-side middle	0xc1
Top-side middle	0xc2
Left-side middle	0xc3
Center-box bar	0xc4
Intersection	0xc5
Double lower left-corner box	0xc8
Double upper left-corner box	0xc9
Double bottom-side middle	0xca
Double top-side middle	0xcb
Double left-side middle	0xcc
Double center-box bar	0xcd
Double intersection	0xce
Small i dotless	0xd5
Lower right-corner box	0xd9
Upper left-corner box	0xda
Bright character cell	0xdb
Bright character cell - lower half	0xde
Bright character cell - upper half	0xdf
Overbar	0xee
Middle dot, Product dot	0xfa
Vertical solid rectangle	0xfe

IBM-856

The available symbols and the layout of code set IBM-856 are covered in this section.

The following figure summarizes the available symbols and shows the layout of Code Set IBM-856. For a textual representation of this code set, see “IBM-856” on page 203.

IBM-943 and IBM-932

Each of the Japanese IBM PC code sets are an encoding consisting of single-byte and multibyte coded characters. The encoding is based on the IBM PC code set and places the JIS characters in shifted positions. This is referred to as *Shift-JIS* or SJIS.

IBM-943 is a newer code set for the Japanese locale than IBM-932. IBM-943 is a compatible code set for the Japanese Microsoft Windows environment. This code set is known as 1983 ordered shift-JIS. The differences between IBM-932 and IBM-943 are as follows:

- Previous JIS sequence (1978 ordered) is applied for IBM-932 while newer JIS sequence (1983 ordered) is applied for IBM-943.
- NEC selected characters are added to IBM-943.
- NEC's IBM selected characters are added to IBM-943.

The IBM-932 code set consists of the following character sets:

Character set	Description
JISCII	JISX0201 Graphic Left character set
JISX0201.1976	Katakana/Hiragana Graphic Right character set
JISX0208.1983	Kanji level 1 and 2 character sets
IBM-udcJP	IBM user-definable characters

The IBM-943 code set consists of the following character sets:

Character set	Description
JISCII	JISX0201 Graphic Left character set
JISX0201.1976	Katakana/Hiragana Graphic Right character set
JISX0208.1990	Kanji level 1 and 2 character sets
IBM-udcJP	IBM user-definable characters and NEC's IBM selected characters and NEC selected characters

The first byte of each character is used to determine the number of bytes for a given character. The values 0x20-0x7e and 0xa1-0xdf are used to encode JISX0201 characters, with exceptions. The positions 0x81-0x9f and 0xe0-0xfc are reserved for use as the first byte of a multibyte character. The JISX0208 characters are mapped to the multibyte values starting at 0x8140. The second byte of a multibyte character can have any value. The Shift-JIS table shows where these characters are located on the code set.

Character Encoding	Code Point	Description	Count
000xxxxx	00–1f	Controls	32
00100000	20	Space	1
0xxxxxxx	21–7E	7-bit ASCII	94
01111111	7F	Delete	1
10000000	80	Undefined	1
100xxxxx 01xxxxxx	[81–9F] [40–7E]	Double byte	1953
100xxxxx 1xxxxxxx	[81–9F] [80–FC]	Double byte	3975
10100000	A0	Undefined	1
1xxxxxxx	A1–DF	7-bit single byte	63
111xxxxx 01xxxxxx	[E0–FC] [40–7E]	Double byte	1827
111xxxxx 1xxxxxxx	[E0–FC] [80–FC]	Double byte	3625
11111101	FD	Undefined	1
11111110	FE	Undefined	1
11111111	FF	Undefined	1

The following table shows the DBCS portion of IBM-943.

Code Point	Description
[81–84] [40–7E] and [81–84] [80–F0]	JIS X 0208 (Non-Kanji)
[87] [40–7E] and [87] [80–F0]	NEC selected characters
[89–98] [40–7E] and [88] [9F–F0], [89–97] [80–F0], [98] [80–9F]	JIS X0208 (Level-1 Kanji)
[99–9F] [40–7E] and [98] [9F–F0], [99–9F] [80–F0]	JIS X0208 (Level-2 Kanji)
[E0–EA] [40–7E] and [E0–EA] [80–F0]	JIS X0208 (Level-2 Kanji)
[ED–EE] [40–7E] and [ED–EE] [80–F0]	NEC IBM selected characters
[F0–F9] [40–7E] and [F0–F9] [80–F0]	User-defined characters
[FA] [40–5C]	IBM selected characters (non-Kanji)
[FA] [5C–7E], [FB–FC] [40–7E] and [FA–FC] [80–F0]	IBM selected characters (Kanji)

The following table shows the DBCS portion of IBM-932.

Code Point	Description
[81-98] [40-7E] and [81-97] [80-FC], [98] [80-9F]	JIS X 0208 (Level-1 Kanji)
[99-9F] [40-7E] and [98] [9F-FC], [99-9F] [80-FC]	JIS X 0208 (Level-2 Kanji)
[E0-EF] [40-7E] and [E0-EF] [80-FC]	JIS X 0208 (Level-2 Kanji)
[F0-F9] [40-7E] and [F0-F9] [80-FC]	User-defined characters
[FA-FC] [40-7E] and [FA-FC] [80-FC]	IBM selected characters

IBM-1046

The available symbols and the layout of code set IBM-1046 are covered in this section.

The following figure summarizes the available symbols and shows the layout of Code Set IBM-1046. For a textual representation of this code set, see “IBM-1046” on page 210.

UCS-2 and UTF-8

AIX provides a set of code sets that address the needs of a particular language or a language group. None of the code sets represented in the ISO8859 family of code sets, the PC code sets, nor the Extended UNIX Code (EUC) code sets allow the mixing of characters from different scripts. With ISO8859-1, you can mix and represent the Latin 1 characters (languages principally spoken in the U.S., Canada, Western Europe, and Latin America). ISO8859-2 covers Eastern European languages; ISO8859-5 covers Cyrillic, ISO8859-6 covers Arabic, ISO8859-7 covers Greek, ISO8859-8 covers Hebrew, ISO8859-9 covers Turkish, IBM-eucJP covers Japanese, IBM-eucKR covers Korean, IBM-eucTW covers Traditional Chinese. The point is that none of the above code sets covers all of the languages.

The International Organization for Standardization (ISO) addressed the limited language coverage by code sets by adopting Unicode as the encoding for the 2-octet form of the ISO10646 Universal Multiple-Octet Coded Character Set (UCS-2). The 32-bit form of ISO10646 is known as UCS-4 for 4-octet form. AIX uses the 16-bit form of ISO10646 and uses the standard label *UCS-2* to describe this encoding.

Although UCS-2 is ideal for an internal process code, it is not suitable for encoding plain text on traditional byte-oriented systems, such as AIX. Therefore, the external file code is The Open Group's File System Safe UCS Transformation Format (FSS-UTF). This transformation format encoding is also known as UTF-8, and *UTF-8* is the label that is used for this encoding on AIX.

Related concepts:

“UTF-8 interchange converters” on page 106

This section will discuss conversions provided in both directions for each code set and UTF-8.

ISO10646 UCS-2 (Unicode)

Universal Coded Character Set (UCS) is the name of the ISO10646 standard that defines a single code for the representation, interchange, processing, storage, entry, and presentation of the written form of all the major languages of the world.

The character code values of UCS-2 are identical to those of the Unicode character encoding standard published by the Unicode Consortium. UCS-2 defines codes for characters used in all major written languages. In addition to a set of scientific, mathematic, and publishing symbols, UCS-2 covers the following scripts:

- Arabic
- Armenian
- Azerbaijani
- Bengali
- Bopomofo
- Cyrillic
- Devanagari
- Georgian
- Greek
- Gujarati
- Gurmukhi
- Hangul
- Chinese Hanzi
- Hebrew
- Hiragana
- International Phonetic Alphabet (IPA)
- Katakana
- Japanese Kanji
- Kannada
- Korean Hanja
- Laotian
- Latin
- Malayalam
- Maltese
- Oriya
- Tamil
- Telugu
- Thai
- Tibetan
- Urdu
- Welsh

The ability of AIX to display characters in the scripts mentioned above is limited to the availability of fonts. AIX provides bitmap fonts for most of the major languages of the world, as well as a Unicode-based scalable TrueType font.

UCS-2 encodes a number of combining characters, also known as non-spacing marks for floating diacritics. These characters are necessary in several scripts including Indic, Thai, Arabic, and Hebrew. The combining characters are used for generating characters in Latin, Cyrillic, and Greek scripts. However, the presence of combining characters creates the possibility for an alternative coding for the same text. Although the coding is unambiguous and data integrity is preserved, the processing of text that contains combining characters is more complex. To provide conformance for applications that choose not to deal with the combining characters, ISO10646 defines the following implementation levels:

Level 1

Does not allow combining characters.

level 2

Allows combining marks from Thai, Indic, Hebrew, and Arabic scripts.

Level 3

Allows combining marks, including ones for Latin, Cyrillic, and Greek.

Note: On the AIX operating system, the ISO10646-1 label refers to UCS-2 encoding. This label can be used as an alias for UCS-2.

UCS-4 and UTF-32

The Unicode standard is used to define standard character encodings for most of the commonly used languages in the world. The 2-byte form of this standard is commonly referred to as *UCS-2*. However, UCS-2 is only capable of representing a maximum of 65,536 characters as a 2-byte quantity. The 4-byte form of Unicode is referred to as *UCS-4* or *UTF-32*, and is capable of defining the complete extensions of Unicode, with a maximum of over 1,000,000 unique characters definable.

UTF-8 (UCS transformation format)

The Open Group has developed a transformation format for UCS designed for use in existing file systems. The intent is that UCS will be the process code for the transformation format, which is usable as a file code.

UTF-8 has the following properties:

- It is a superset of ASCII, in which the ASCII characters are encoded as single-byte characters with the same numeric value.
- No ASCII code values occur in multibyte characters, other than those that represent the ASCII characters.
- The first byte of a character indicates the number of bytes to follow in the multibyte character sequence and cannot occur anywhere else in the sequence.

The UTF-8 encodes UCS values in the 0 through 0x7FFFFFFF range using multibyte characters with lengths of 1, 2, 3, 4, 5, and 6 bytes. Single-byte characters are reserved for the ASCII characters in the 0 through 0x7f range. These characters all have the high order bit set to 0. For all character encodings of more than one byte, the initial byte determines the number of bytes used, and the high-order bit in each byte is set. Every byte that does not start with the bit combination of 10xxxxxx, where x represents a bit that may be 0 or 1, is the start of a UCS character sequence. The following table provides UTF-8 multibyte codes:

Bytes	Bits	Hex Minimum	Hex Maximum	Byte Sequence in Binary
1	7	00000000	0000007F	0xxxxxxx
2	11	00000080	000007FF	110xxxxx 10xxxxxx
3	16	00000800	0000FFFF	1110xxxx 10xxxxxx 10xxxxxx
4	21	00010000	001FFFFF	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx
5	26	00200000	03FFFFFF	111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
6	31	04000000	7FFFFFFF	1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx

The UCS value is just the concatenation of the x bits in the multibyte encoding. When there are multiple ways to encode a value (for example, UCS 0), only the shortest encoding is permitted.

The following subset of UTF-8 is used to encode UCS-2:

Bytes	Bits	Hex Minimum	Hex Maximum	Byte Sequence in Binary
1	7	00000000	0000007F	0xxxxxxx
2	11	00000080	000007FF	110xxxxx 10xxxxxx
3	16	00000800	0000FFFF	1110xxxx 10xxxxxx 10xxxxxx

This subset of UTF-8 requires a maximum of three (3) bytes.

UTF-16

UTF-16 is the UCS Transformation Format for 16 planes of Group 00. UTF-16 is the ISO/IEC encoding that is equivalent to the Unicode Standard with the use of surrogates. In UTF-16, each UCS-2 code value represents itself. Non-BMP code values of ISO/EIC 10646 in planes 1..16 are represented using pairs of special codes. UTF-16 defines the transformation between the UCS-4 code positions in planes 1 to 16 of Group 00 and the pairs of special codes, and is identical to the transformation defined in the Unicode Standard.

Converters overview for programming

Multicultural support provides a base for globalization in which data often can be changed from one code set to another. Support of several standard converters for this purpose is provided.

Data sent by one program to another program residing on a remote host may require conversion from the code set of the source machine to that of the receiver. For example, when communicating with a VM system, the workstation converts its ISO8859-1 data to an EBCDIC form.

Code sets define graphic characters and control character assignments to code points. These coded characters must also be converted when a program obtains data in one code set but displays it in another code set.

The system provides the following conversion interfaces:

iconv command

Allows you to request a specific conversion by naming the *FromCode* and *ToCode* code sets.

libiconv functions

Allows applications to request converters by name.

The system provides ready-to-use libraries of converters. The converter libraries are found in the `/usr/lib/nls/loc/iconv/*` and `/usr/lib/nls/loc/iconvTable/*` directories. Do not define your own converter unless absolutely necessary.

In addition to code set converters, the converter library also provides a set of network interchange converters. In a network environment, the code sets of the communications systems and the protocols of communication determine how the data should be converted.

Interchange converters are used to convert data sent from one system to another. Conversions from one internal code set to another code set require code set converters. When data must be converted from a sender's code set to a receiver's code set or from 8-bit data to 7-bit data, a uniform interface is required. The `iconv` subroutines provide this interface.

Related concepts:

“Conversion between code sets” on page 2

A character is any symbol that is used for the organization, control, or representation of data. A group of such symbols that are used to describe a particular language make up a character set. A code set contains the encoding values for a character set. The encoding values in a code set provide an interface between the system and its input and output devices. Multicultural support supplies converters that conform to character-encoding values that are found in different code sets.

“Converters overview” on page 2

Globalization provides a base for globalization to allow data to be changed from one code set to another. You might need to convert text files or message catalogs. There are several standard converters for this purpose.

“Understanding libiconv”

The section will cover the `iconv` application programming interface (API) conversion.

Using the `iconv` command

Any converter installed in the system can be used through the `iconv` command, which uses the `iconv` library.

The `iconv` command acts as a filter for converting from one code set to another. For example, the following command filters data from PC Code (IBM-850) to ISO8859-1:

```
cat File | iconv -f IBM-850 -t ISO8859-1 | tftp -p - host /tmp/fo
```

The `iconv` command converts the encoding of characters read from either standard input or the specified file and then writes the results to standard output.

Note: On the AIX operating system, the ISO10646-1 label refers to UCS-2 encoding. This label can be used as an alias for UCS-2.

Understanding libiconv

The section will cover the `iconv` application programming interface (API) conversion.

Often The `iconv` application programming interface (API) consists of the following subroutines that accomplish conversion:

`iconv_open`

Performs the initialization required to convert characters from the code set specified by the *FromCode* parameter to the code set specified by the *ToCode* parameter. The strings specified are dependent on the converters installed in the system. If initialization is successful, the converter descriptor, `iconv_t`, is returned in its initial state.

iconv Invokes the converter function using the descriptor obtained from the `iconv_open` subroutine. The *inbuf* parameter points to the first character in the input buffer, and the *inbytesleft* parameter indicates the number of bytes to the end of the buffer being converted. The *outbuf* parameter

points to the first available byte in the output buffer, and the *outbytesleft* parameter indicates the number of available bytes to the end of the buffer.

For state-dependent encoding, the subroutine is placed in its initial state by a call for which the *inbuf* value is a null pointer. Subsequent calls with the *inbuf* parameter as something other than a null pointer cause the internal state of the function to be altered as necessary.

iconv_close

Closes the conversion descriptor specified by the *cd* variable and makes it usable again

In a network environment, the following factors determine how data should be converted:

- Code sets of the sender and the receiver
- Communication protocol (8-bit or 7-bit data)

The following table outlines the conversion methods and recommends how to convert data in different situations.

Table 5. Communication with system using the same code set

Criteria	Communication protocol	Communication protocol
Method to choose	7-bit only	8-bit
as is	Not valid	Best choice
fold7	OK	OK
fold8	Not valid	OK
uucode	Best choice	OK

Table 6. Communication with system using different code set (or receiver's code set is unknown)

Criteria	Communication protocol	Communication protocol
Method to choose	7-bit only	8-bit
as is	Not valid	Not valid if remote code set is unknown
fold7	Best choice	OK
fold8	Not valid	Best choice
uucode	Not valid	Not valid

If the sender uses the same code set as the receiver, the following possibilities exist:

- When protocol allows 8-bit data, the data can be sent without conversions.
- When protocol allows only 7-bit data, the 8-bit code points must be mapped to 7-bit values. Use the **iconv** interface and one of the following methods:

Method	Description
uucode	Provides the same mapping as the uuencode and uudencode commands. This is the recommended method.
7-bit	Converts internal code sets using 7-bit data. This method passes ASCII without any change.

If the sender uses a code set different from the receiver, there are two possibilities:

- When protocol allows only 7-bit data, use the **fold7** method.
- When protocol allows 8-bit data and you know the receiver's code set, use the **iconv** interface to convert the data. If you do not know the receiver's code set, use the following method:

Method	Description
8-bit	Converts internal code sets to standard interchange formats. The 8-bit data is transmitted and the information is preserved so that the receiver can reconstruct the data in its code set.

Related concepts:

“Converters overview for programming” on page 81

Multicultural support provides a base for globalization in which data often can be changed from one code set to another. Support of several standard converters for this purpose is provided.

“Interchange converters—7-bit” on page 96

This converter provides conversion between internal code and 7-bit standard interchange formats (fold7).

“Interchange converters—8-bit” on page 98

This converter provides conversions between internal code and 8-bit standard interchange formats (fold8).

“Interchange converters—uucode” on page 103

This converter provides the same mapping as the **uuencode** and **uudecode** commands.

Using the `iconv_open` subroutine

This section will illustrate how to use the `iconv_open` subroutine in different situations.

The following examples illustrate how to use the `iconv_open` subroutine in different situations:

- When the sender and receiver use the same code sets, and if the protocol allows 8-bit data, you can send data without converting it. If the protocol allows only 7-bit data, do the following:

Sender:

```
cd = iconv_open("uucode", nl_langinfo(CODESET));
```

Receiver:

```
cd = iconv_open(nl_langinfo(CODESET), "uucode");
```

- When the sender and receiver use different code sets, and if the protocol allows 8-bit data and the receiver's code set is unknown, do the following

Sender:

```
cd = iconv_open("fold8", nl_langinfo(CODESET));
```

Receiver:

```
cd = iconv_open(nl_langinfo(CODESET), "fold8" );
```

If the protocol allows only 7-bit data, do the following:

Sender:

```
cd = iconv_open("fold7", nl_langinfo(CODESET));
```

Receiver:

```
cd = iconv_open(nl_langinfo(CODESET), "fold7" );
```

The `iconv_open` subroutine uses the `LOCPATH` environment variable to search for a converter whose name is in the following form:

`iconv/FromCodeSet_ToCodeSet`

The `FromCodeSet` string represents the sender's code set, and the `ToCodeSet` string represents the receiver's code set. The underscore character separates the two strings.

Note: All `setuid` and `setgid` programs ignore the `LOCPATH` environment variable.

Because the **iconv** converter is a loadable object module, a different object is required when running in the 64-bit environment. In the 64-bit environment, the **iconv_open** routine uses the **LOCPATH** environment variable to search for a converter whose name is in the following form:

```
iconv/FromCodeSet_ToCodeSet__64.
```

The **iconv** library automatically chooses whether to load the standard converter object or the 64-bit converter object. If the **iconv_open** subroutine does not find the converter, it uses the **from,to** pair to search for a file that defines a table-driven conversion. The file contains a conversion table created by the **genxlt** command.

The **iconvTable** converter uses the **LOCPATH** environment variable to search for a file whose name is in the following form:

```
iconvTable/FromCodeSet_ToCodeSet
```

If the converter is found, it performs a load operation and is initialized. The converter descriptor, **iconv_t**, is returned in its initial state.

Converter programs versus tables

Converter programs are executable functions that convert data according to a set of rules. Converter tables are single-byte conversion tables that perform stateless conversions.

Programs and tables are in separate directories, as follows:

Directory	Description
<code>/usr/lib/nls/loc/iconv</code>	Converter programs
<code>/usr/lib/nls/loc/iconvTable</code>	Converter tables

After a converter program is compiled and linked with the **libiconv.a** library, the program is placed in the `/usr/lib/nls/loc/iconv` directory.

To build a table converter, build a source converter table file. Use the **genxlt** command to compile translation tables into a format understood by the table converter. The output file is then placed in the `/usr/lib/nls/loc/iconvTable` directory.

Unicode and universal converters

This section will cover unicode conversion tables and universal converter programs.

Unicode (or UCS-2) conversion tables are found in:

```
$LOCPATH/uconvTable/*CodeSet*
```

The `$LOCPATH/uconv/UCSTBL` converter program is used to perform the conversion to and from UCS-2 using the **iconv** utilities.

A universal converter program is provided that can be used to convert between any two code sets whose conversions to and from UCS-2 is defined. Given the following **uconv** tables:

```
X    -> UCS-2
UCS-2 -> Y
```

A universal conversion can be defined that maps the following:

```
X -> UCS-2 -> Y
```

by use of the `$LOCPATH/iconv/Universal_UCS_Conv`.

Universal UCS converter

UCS-2 is a universal 16-bit encoding that can be used as an interchange medium to provide conversion capability between virtually any code sets.

The conversion can be accomplished using the Universal UCS Converter, which converts between any two code sets XXX and YYY as follows:

```
XXX <-> UTF-32 <-> YYY
```

The XXX and YYY conversions must be included in the supported List of UCS-2 Interchange Converters, and must be installed on the system.

The universal converter is installed as the file `/usr/lib/nls/loc/iconv/Universal_UCS_Conv`.

The conversion between multibyte and wide character code depends on the current locale setting. Do not exchange wide character codes between two processes, unless you have knowledge that each locale that might be used handles wide character codes in a consistent fashion. Most locales for this operating system use the Unicode character value as a wide character code, except locales based on IBM-eucTW code sets.

Using converters

This section will cover the iconv interface subroutines.

The iconv interface is a set of the following subroutines used to open, perform, and close conversions:

- `iconv_open`
- `iconv`
- `iconv_close`

Code set conversion filter example

This section will cover a code set conversion filter that accepts the *ToCode* and *FromCode* parameters.

The following example shows how you can use these subroutines to create a code set conversion filter that accepts the *ToCode* and *FromCode* parameters as input arguments:

```
#include <stdio.h>
#include <nls_types.h>
#include <iconv.h>
#include <string.h>
#include <errno.h>
#include <locale.h>

#define ICONV_DONE() (r>=0)
#define ICONV_INVALID() (r<0) && (errno==EILSEQ))
#define ICONV_OVER() (r<0) && (errno==E2BIG))
#define ICONV_TRUNC() (r<0) && (errno==EINVAL))

#define USAGE 1
#define ERROR 2
#define INCOMP 3

char ibuf[BUFSIZ], obuf[BUFSIZ];

extern int errno;

main (argc,argv)
int argc;
char **argv;
{
```

```

size_t ileft,oleft;
nl_catd catd;
iconv_t cd;
int r;
char *ip,*op;

setlocale(LC_ALL,"");
catd = catopen (argv[0],0);

if(argc!=3){
    fprintf(stderr,
        catgets (catd,NL_SETD,USAGE,"usage:conv fromcode tocode\n"));
    exit(1);
}

cd=iconv_open(argv[2],argv[1]);

ileft=0;

while(!feof(stdin)) {
    /*
    * After the next operation,ibuf will
    * contain new data plus any truncated
    * data left from the previous read.
    */
    ileft+=fread(ibuf+ileft,1,BUFSIZ-ileft,stdin);
    do {
        ip=ibuf;
        op=obuf;
        oleft=BUFSIZ;

        r=iconv(cd,&ip,&ileft,&op,&oleft);

        if(ICONV_INVALID()){
            fprintf(stderr,
                catgets(catd,NL_SETD,ERROR,"invalid input\n"));
            exit(2);
        }

        fwrite(obuf,1,BUFSIZ-oleft,stdout);

        if(ICONV_TRUNC() || ICONV_OVER())
            /*
            *Data remaining in buffer-copy
            *it to the beginning
            */

            memcpy(ibuf,ip,ileft);

        /*
        *loop until all characters in the input
        *buffer have been converted.
        */
    } while(ICONV_OVER());
}

if(ileft!=0){
    /*
    *This can only happen if the last call
    *to iconv() returned ICONV_TRUNC, meaning
    *the last data in the input stream was
    *incomplete.
    */
    fprintf(stderr,catgets(catd,NL_SETD,INCOMP,"input incomplete\n"));
    exit(3);
}

```

```

iconv_close(cd);
exit(0);
}

```

Naming converters

This section covers code set names.

Code set names are in the form *CodesetRegistry-CodesetEncoding* where:

Code set form	Description
<i>CodesetRegistry</i>	Identifies the registration authority for the encoding. The <i>CodesetRegistry</i> must be made of characters from the portable code set (usually A-Z and 0-9).
<i>CodesetEncoding</i>	Identifies the coded character set defined by the registered authority.

The *from,to* variable used by the **iconv** command and **iconv_open** subroutine identifies a file whose name should be in the form */usr/lib/nls/loc/iconv/%f_%t* or */usr/lib/nls/loc/iconvTable/%f_%t*, where:

Variable	Description
<i>%f</i>	Represents the <i>FromCode</i> set name
<i>%t</i>	Represents the <i>ToCode</i> set name

List of converters

Converters change data from one code set to another. The sets of converters supported with the **iconv** library are listed in the following sections.

All converters shipped with the BOS Runtime Environment are located in the **/usr/lib/nls/loc/iconv/*** or **/usr/lib/nls/loc/iconvTable/*** directory.

These directories also contain *private* converters; that is, they are used by other converters. However, users and programs should only depend on the converters in the following lists.

Any converter shipped with the BOS Runtime Environment and not listed here should be considered private and subject to change or deletion. Converters supplied by other products can be placed in the **/usr/lib/nls/loc/iconv/*** or **/usr/lib/nls/loc/iconvTable/*** directory.

Programmers are encouraged to use registered code set names or code set names associated with an application. The X Consortium maintains a registry of code set names for reference.

Related concepts:

“Code sets for multicultural support” on page 47

The globalization of AIX is based on the assumption that all code sets can be divided into any number of character sets.

PC, ISO, and EBCDIC code set converters

These converters provide conversion between PC, ISO, and EBCDIC single-byte stateless code sets. The following types of conversions are supported: PC to/from ISO, PC to/from EBCDIC, and ISO to/from EBCDIC.

Conversion is provided between compatible code sets such as Latin-1 to Latin-1 and Greek to Greek. However, conversion between different EBCDIC national code sets is not supported. For information about converting between incompatible character sets.

Conversion tables in the `iconvTable` directory are created by the `genxlt` command.

Related concepts:

“Interchange converters—7-bit” on page 96

This converter provides conversion between internal code and 7-bit standard interchange formats (fold7).

“Interchange converters—8-bit” on page 98

This converter provides conversions between internal code and 8-bit standard interchange formats (fold8).

Related information:

`genxlt` command

Compatible code set names

The following table lists code set names that are compatible. Each line defines to/from strings that may be used when requesting a converter.

Note: The PC and ISO code sets are ASCII-based.

Table 7. Code Set Compatibility

Character Set	Languages	PC	ISO	EBCDIC
Latin-1	U.S. English, Portuguese, Canadian French	N/A	ISO8859-1	IBM-037
Latin-1	Danish, Norwegian	N/A	ISO8859-1	IBM-277
Latin-1	Finnish, Swedish	N/A	ISO8859-1	IBM-278
Latin-1	Italian	N/A	ISO8859-1	IBM-280

Multibyte code set converters

This section describes the code sets that multibyte code set converters use to convert.

Multibyte code set converters convert characters among the following code sets:

- PC multibyte code sets
- EUC multibyte code sets (ISO-based)
- EBCDIC multibyte code sets

The following table lists code set names that are compatible. Each line defines to/from strings that may be used when requesting a converter.

Table 9. *Code Set Compatibility*

Language	PC	ISO	EBCDIC
Japanese	IBM-932	IBM-eucJP	IBM-930, IBM-939
Japanese (MS compatible)	IBM-943	IBM-eucJP	IBM-930, IBM-939
Korean	IBM-934	IBM-eucKR	IBM-933
Traditional Chinese	IBM-938, big-5	IBM-eucTW	IBM-937
Simplified Chinese	IBM-1381	IBM-eucCN	IBM-935

1. Conversions between Simplified and Traditional Chinese are provided (IBM-eucTW <—> IBM-eucCN and big5 <—> IBM-eucCN).
2. UTF-8 is an additional code set.

Related concepts:

“UTF-8 interchange converters” on page 106

This section will discuss conversions provided in both directions for each code set and UTF-8.

Files

The following list describes the Multibyte Code Set converters that are found in the `/usr/lib/nls/loc/iconv` directory.

Interchange converters—7-bit

This converter provides conversion between internal code and 7-bit standard interchange formats (fold7).

The fold7 name identifies encodings that can be used to pass text data through 7-bit mail protocols. The encodings are based on ISO2022.

The fold7 converters convert characters from a code set to a canonical 7-bit encoding that identifies each character. This type of conversion is useful in networks where clients communicate with different code sets but use the same character sets. For example:

Code set conversion	Description
IBM-850 <—> ISO8859-1	Common Latin characters
IBM-932 <—> IBM-eucJP	Common Japanese characters

The following escape sequences designate standard code sets:

Escape sequence	Standard code set
01/11 02/04 04/00	GL JIS X0208.1978-0.
01/11 02/04 02/08 04/01	GL left half of GB2312.1980-0.
01/11 02/08 04/02	GL 7-bit ASCII or left half of ISO8859-1.
01/11 02/14 04/01	GL right half of ISO8859-1.
01/11 02/14 04/02	GL right half of ISO8859-2.
01/11 02/14 04/03	GL right half of ISO8859-3.
01/11 02/14 04/04	GL right half of ISO8859-4.
01/11 02/14 04/06	GL right half of ISO8859-7.
01/11 02/14 04/07	GL right half of ISO8859-6.
01/11 02/14 04/08	GL right half of ISO8859-8.
01/11 02/14 04/12	GL right half of ISO8859-5.
01/11 02/14 04/13	GL right half of ISO8859-9.
01/11 02/08 04/09	GL right half of JIS X0201.1976-0.
01/11 02/08 04/10	GL left half of JIS X0201.1976.
01/11 02/04 04/02	GL JIS X0208.1983-0.
01/11 02/04 02/08 04/02	GL JIS X0208.1983-0.
01/11 02/04 02/08 04/00	GL JISX0208.1978-0.

Escape sequence	Standard code set
01/11 02/05 02/15 03/01 M L 06/09 06/02 06/13 02/13 03/08 03/05 03/00 00/02	GL right half of IBM-850 unique characters. Characters common to ISO8859-1 do not use this escape sequence.
01/11 02/05 02/15 03/02 M L 06/09 06/02 06/13 02/13 07/05 06/04 06/03 04/10 05/00 00/02	GL Japanese) IBM-udcJP) user-definable characters.
01/11 02/04 02/08 04/03	GL KSC5601-1987.
01/11 02/04 02/09 03/00	GL CNS11643-1986-1.
01/11 02/04 02/10 03/01	GL CNS11643-1986-2.
01/11 02/05 02/15 03/00 M L 05/05 05/04 04/06 02/13 03/07 00/02	UCS-2 encoded as base64; used only for those characters not encoded by any of the other 7-bit escape sequences listed above.

When converting from a code set to fold7, the escape sequence used to designate the code set is chosen according to the order listed. For example, the JISX0208.1983-0 characters use **01/11 01/04 04/02** as the designation.

Interchange converters—8-bit

This converter provides conversions between internal code and 8-bit standard interchange formats (fold8).

The fold8 name identifies encodings that can be used to pass text data through 8-bit mail protocols. The encodings are based on ISO2022.

The fold8 converters convert characters from a specific code set encoding to a canonical 8-bit encoding that identifies each character. This type of conversion is useful in networks where clients communicate with different code sets but use the same character sets. For example:

Code set conversion	Description
IBM-850 <—> ISO8859-1	Common Latin characters
IBM-932 <—> IBM-eucJP	Common Japanese characters

The following escape sequences designate standard code sets.

Escape Sequence	Standard Code Set
01/11 02/04 02/09 04/01	GR right half of GB2312.1980-0.
01/11 02/13 04/01	GR right half of ISO8859-1.
01/11 02/13 04/02	GR right half of ISO8859-2.
01/11 02/13 04/03	GR right half of ISO8859-3.
01/11 02/13 04/04	GR right half of ISO8859-4.
01/11 02/13 04/06	GR right half of ISO8859-7.
01/11 02/13 04/07	GR right half of ISO8859-6.
01/11 02/13 04/08	GR right half of ISO8859-8.
01/11 02/13 04/13	GR right half of ISO8859-5.
01/11 02/13 04/13	GR right half of ISO8859-9.
01/11 02/09 04/09	GR right half of JIS X0201.1976-1.
01/11 02/04 02/09 04/02	GR JIS X0208.1983-1.
01/11 02/04 02/09 04/00	GR JISX0208.1978-1.
01/11 02/09 04/02	GR 7-bit ASCII or left half of ISO8859-1.
01/11 02/05 02/15 03/01 M L 04/09 04/02 04/13 02/13 03/08 03/05 03/00 00/02	GR right half of IBM-850 unique characters. Characters common to ISO8859-1 should not use this escape sequence.
01/11 02/05 02/15 03/02 M L 04/09 04/02 04/13 02/13 07/05 06/04 06/03 04/10 05/00 00/02	GR right half of Japanese user-definable characters.
01/11 02/08 04/02	GL 7-bit ASCII or left half of ISO8859-1.
01/11 02/14 04/01	GL right half of ISO8859-1.
01/11 02/14 04/02	GL right half of ISO8859-2.
01/11 02/14 04/03	GL right half of ISO8859-3.

Interchange converters—compound text

Compound text interchange converters convert between compound text and internal code sets.

Compound text is an interchange encoding defined by the X Consortium. It is used to communicate text between X clients. Compound text is based on ISO2022 and can encode most character sets using standard escape sequences. It also provides extensions for encoding private character sets. The supported code sets provide a converter to and from compound text. The name used to identify the compound text encoding is ct.

The following escape sequences are used to designate standard code sets in the order listed below.

01/11 02/05 02/15 03/01 M L 04/09 04/02 04/13 02/13 03/08 03/05 03/00 00/02

GR right half of IBM-850 unique characters. Characters common to ISO8859-1 should not use this escape sequence.

01/11 02/05 02/15 03/02 M L 04/09 04/02 04/13 02/13 07/05 06/04 06/03 04/10 05/00 00/02

GR right half of Japanese user-definable characters.

01/11 02/05 02/15 03/01 M L 06/09 06/02 06/13 02/13 03/08 03/05 03/00 00/02

GL right half of IBM-850 unique characters. Characters common to ISO8859-1 do not use this escape sequence.

01/11 02/05 02/15 03/02 M L 06/09 06/02 06/13 02/13 07/05 06/04 06/03 04/10 05/00 00/02

GL Japanese (IBM-udcJP) user-definable characters.

GBK_ct	GBK to interchange format

Interchange converters—uucode

This converter provides the same mapping as the **uucode** and **uudecode** commands.

During conversion from uucode, 62 bytes at a time (including a new-line character trailing the record) are converted, and generating 45 bytes in *outbuf*.

UCS-2 interchange converters

UCS-2 uses a universal 16-bit encoding. Conversions for each code set are provided in both directions, between the code set and UCS-2.

UCS-2 converters are found in `/usr/lib/nls/loc/uconvTable` and `/usr/lib/nls/loc/uconv` directories. The `uconvdef` command is used to generate new converters or to customize existing UCS-2 converters.

UTF-8 interchange converters

This section will discuss conversions provided in both directions for each code set and UTF-8.

UTF-8 is a universal, multibyte encoding. Conversions for each code set are provided in both directions, between the code set and UTF-8.

UTF-8 conversions are usually done by using the `Universal_UCS_Conv` and `/usr/lib/nls/loc/uconv/UTF-8` converter.

“Multibyte code set converters” on page 92

This section describes the code sets that multibyte code set converters use to convert.

“UCS-2 and UTF-8” on page 78

AIX provides a set of code sets that address the needs of a particular language or a language group. None of the code sets represented in the ISO8859 family of code sets, the PC code sets, nor the Extended UNIX Code (EUC) code sets allow the mixing of characters from different scripts. With ISO8859-1, you can mix and represent the Latin 1 characters (languages principally spoken in the U.S., Canada, Western Europe, and Latin America). ISO8859-2 covers Eastern European languages; ISO8859-5 covers Cyrillic, ISO8859-6 covers Arabic, ISO8859-7 covers Greek, ISO8859-8 covers Hebrew, ISO8859-9 covers Turkish, IBM-eucJP covers Japanese, IBM-eucKR covers Korean, IBM-eucTW covers Traditional Chinese. The point is that none of the above code sets covers all of the languages.

“UCS-2 interchange converters” on page 104

UCS-2 uses a universal 16-bit encoding. Conversions for each code set are provided in both directions, between the code set and UCS-2.

Miscellaneous converters

A set of low-level converters used by the code set and interchange converters is provided. These converters are called *miscellaneous converters*. These low-level converters may be used by some of the interchange converters. However, the use of these converters is discouraged because they are intended for support of other converters.

Files

This list describes the miscellaneous converters found in the `/usr/lib/nls/loc/iconv` and `/usr/lib/nls/loc/iconvTable` directories.

Writing converters using the iconv interface

This section provides information about the `iconv` subroutines and structures in preparation for writing code set converters. Included in this discussion are an overview of the control flow and the order in which the framework operates, details about writing code set converters, and an example including the code, header file, and a makefile. This section applies to the `iconv` framework within AIX.

Under the framework of the `iconv_open`, `iconv` and `iconv_close` subroutines, you can create and use several different types of converters. Applications can call these subroutines to convert characters in one code set into characters in a different code set. The access and use of the `iconv_open`, `iconv` and `iconv_close` subroutines is standardized by .X/Open Portability Guide Issue 4.

Code sets and converters

Code sets can be classified into two categories: stateful encodings and stateless encodings.

Stateful code sets and converters

The stateful encodings use shift-in and shift-out codes to change state. Shift-out can be used to indicate the start of host double-byte data in a data stream of characters, and shift-in can be used to indicate the end of this double-byte character data. When the double-byte data is off, it signals the start of single-byte character data. An example of such a stateful code set is IBM-930 used mainly on mainframes (hosts).

Converters written to do the conversion of stateful encodings to other code sets tend to be complex because of the extra processing needed.

Stateless code sets and converters

The section will discuss stateless code sets and converters.

The stateless code sets are those that can be classified as one of the following types:

- Single-byte code sets, such as ISO8859 family (ISO8859-1, ISO8859-2, and so on)
- Multibyte code sets, such as IBM-eucJP (Japanese), IBM-932 (Shift-JIS).

Note that conversions are meaningful only if the code sets represent the same characters.

The simplest types of code-set conversion can be found in single-byte code set converters, such as the converter from ISO8859-1 to IBM-850. These single-byte code set converters are based on simple table-based conversions. The conversion of multibyte character encodings, such as IBM-eucJP to IBM-932, are in general based on an algorithm and not on tables, because the tables can get lengthy.

Overview of iconv framework structures

The **iconv** framework consists of the **iconv_open**, **iconv** and **iconv_close** subroutines, and is based on a common core structure that is part of all converters. The core structure is initialized at the load time of the converter object module. After the loading of the converter is complete, the main entry point, which is always the **instantiate** subroutine, is invoked. This initializes the core structure and returns the core converter descriptor. This is further used during the call to the **init** subroutine provided by the converter to allocate the converter-specific structures. This **init** subroutine returns another converter descriptor that has a pointer to the core converter descriptor. The **init** subroutine allocates memory as needed and may invoke other converters if needed. The **init** subroutine is the place for any converter-specific initialization, whereas the **instantiate** subroutine is a generic entry point.

After the converter descriptor for this converter is allocated and initialized, the next step is to provide the actual code needed for the **exec** part of the functionality. If the converter is a table-based converter, the only need is to provide a source file format that conforms to the input needs of the **genxlt** utility, which takes this source table as the input and generates an output file format usable by the **iconv** framework.

iconv.h file and structures

This section describes the **iconv.h** file and its structures.

The **iconv.h** file in **/usr/include** defines the following structures:

```
typedef struct __iconv_rec  iconv_rec, *iconv_t;
struct __iconv_rec  {
    _LC_object_t  hdr;
    iconv_t (*open)(const char *tocode, const char *fromcode);
    size_t (*exec)(iconv_t cd, char **inbuf, size_t *inbytesleft,
                  char **outbuf, size_t *outbytesleft);
    void (*close)(iconv_t cd);
};
```

The common core structure is as follows (**/usr/include/iconv.h**):

```

typedef struct _LC_core_iconv_type      _LC_core_iconv_t;
struct _LC_core_iconv_type {
    _LC_object_t  hdr;
    /* implementation initialization */
    _LC_core_iconv_t      *(*init)();
    size_t      (*exec)();
    void      (*close)();
};

```

Every converter has a static memory area, which contains the `_LC_core_iconv_t` structure. It is initialized in the `instantiate` subroutine provided as part of the converter program.

iconv control flow

An application invokes a code set converter by the following call:

```
iconv_open(char *to_codeset, char *from_codeset)
```

The *to* and *from* code sets are used in selecting the converter by way of the search path defined by the `LOCPATH` environment variable. The `iconv_open` subroutine uses the `_lc_load` subroutine to load the object module specified by concatenating the *from* and *to* code set names to the `iconv_open` subroutine. `CONVERTER NAME= "from_codeset" + "_" + "to_codeset"`

If the *from_codeset* is IBM-850 and the *to_codeset* is ISO8859-1, the converter name is IBM-850_ISO8859-1.

After loading the converter, its entry point is invoked by the `_lc_load` loader subroutine. This is the first call to the converter. The `instantiate` subroutine then initializes the `_LC_core_iconv_t` core structure. The `iconv_open` subroutine then calls the `init` subroutine associated with the core structure thus returned. The `init` subroutine allocates the converter-specific descriptor structure and initializes it as needed by the converter. The `iconv_open` subroutine returns this converter-specific structure. However, the return value is typecast to `iconv_t` in the user's application. Thus, the application does not see the whole of the converter-specific structure; it sees only the public `iconv_t` structure. The converter code itself uses the private converter structure. Applications that use `iconv` converters should not change the converter descriptor; the converter descriptor should be used as an opaque structure.

An *entry point* is declared in every converter so that when the converter is opened by a call to the `iconv_open` subroutine, that entry point is automatically invoked. The entry point is the `instantiate` subroutine that should be provided in all converters. The entry point is specified in the makefile as follows:

```
LDENTRY=-einstantiate
```

When the converter is loaded on a call to the `iconv_open` subroutine, the `instantiate` subroutine is invoked. This subroutine initializes a static core conversion descriptor structure `_LC_core_iconv_t cd`.

The core conversion descriptor `cd` contains pointers to the `init`, `_iconv_exec`, and `_iconv_close` subroutines supplied by the specific converter. The `instantiate` subroutine returns the core conversion descriptor to be used later. The `_LC_core_iconv_t` structure is defined in `/usr/include/iconv.h`.

When the `iconv_open` subroutine is called, the following actions occur:

1. The converter is found using the `LOCPATH` environment variable, the converter is loaded, and the `instantiate` subroutine is invoked. On success, it returns the core conversion descriptor. (`_LC_core_iconv_t *cd`). The `instantiate` subroutine provided by the converter is responsible for initializing the header in the core structure.
2. The `iconv_open` subroutine then invokes the `init` subroutine specified in the core conversion descriptor. The `init` subroutine provided by the converter is responsible for allocation of memory needed to hold the converter descriptor needed for this specific converter. For example, the following might be the structure needed by a stateless converter:

```
typedef struct _LC_sample_iconv_rec {
    LC_core_iconv_t    core;

    } _LC_sample_iconv_t;
```

To initialize this, the converter has to do the following in the `init` subroutine:

```
static _LC_sample_iconv_t*
init (_LC_core_iconv_t *core_cd, char* toname, char* fromname)
{
    _LC_sample_iconv_t    *cd;    /* converter descriptor */

    /*
    **      Allocate a converter descriptor
    **/
    if(!(cd = (_LC_sample_iconv_t *) malloc (
        sizeof(_LC_sample_iconv_t ))))
        return (NULL);

    /*
    ** Copy the core part of converter descriptor which is
    ** passed in
    **/
    cd->core = *core_cd;
    /*
    **      Return the converter descriptor
    **/
    return cd;
}
```

An application invokes the `iconv` subroutine to do the actual code set conversions. The `iconv` subroutine invokes the `exec` subroutine in the core structure.

An application invokes the `iconv_close` subroutine to free any memory allocated for conversions. The `iconv_close` subroutine invokes the `close` subroutine in the core structure.

Writing a code set converter

This section provides information on how to write a converter using the concepts that have already been explained.

Every converter should define the following subroutines:

- **instantiate**
- **init**
- **iconv_exec**
- **iconv_close**

The converter-specific structure should have the core `iconv` structure as its first element. For example:

```
typedef struct _LC_example_rec {
    /* Core should be the first element */
    LC_core_iconv_t    core;
    /* The rest are converter specific data (optional) */
    iconv_t            curcd;
    iconv_t            sb_cd;
    iconv_t            db_cd;
    unsigned char      *cntl;
} _LC_example_iconv_t;
```

Another converter structure:

```

typedef struct _LC_sample_iconv_rec {
    _LC_core_iconv_t      core;
} _LC_sample_iconv_t;

```

Algorithm-based stateless converters

Every converter should have the subroutines previously specified. Only the subroutine headers are provided without details, except for the **instantiate** subroutine that is common to all converters and should be coded in the same way.

The following example of an algorithm-based stateless converter is a sample converter of the IBM-850 code set to the ISO8859-1 code set.

```

#include <stdlib.h>
#include <iconv.h>
#include "850_88591.h"
/*
 *   Name :  _iconv_exec()
 *
 *   This contains actual conversion method.
 */
static size_t  _iconv_exec(_LC_sample_iconv_t *cd,
                          unsigned char** inbuf,
                          size_t *inbytesleft,
                          unsigned char** outbuf,
                          size_t *outbytesleft)
/*
 *   cd           :  converter descriptor
 *   inbuf        :  input buffer
 *   outbuf       :  output buffer
 *   inbytesleft  :  number of data(in bytes) in input buffer
 *   outbytesleft :  number of data(in bytes) in output buffer
 */
{
}

/*
 *   Name :  _iconv_close()
 *
 *   Free the allocated converter descriptor
 */
static void  _iconv_close(iconv_t cd)
{
}

/*
 *   Name :  init()
 *
 *   This allocates and initializes the converter descriptor.
 */
static _LC_sample_iconv_t  *init (_LC_core_iconv_t *core_cd,
                                  char* toname, char* fromname)
{
}

/*
 *   Name :  instantiate()
 *
 *   Core part of a converter descriptor is initialized here.
 */
_LC_core_iconv_t  *instantiate(void)
{
    static _LC_core_iconv_t  cd;

    /*
     * * Initialize _LC_MAGIC and _LC_VERSION are

```

```

** defined in <lc_core.h>. _LC_ICONV and _LC_core_iconv_t
** are defined in <iconv.h>.
*/
cd.hdr.magic = _LC_MAGIC;
cd.hdr.version = _LC_VERSION;
cd.hdr.type_id = _LC_ICONV;
cd.hdr.size = sizeof (_LC_core_iconv_t);

/*
 *      Set pointers to each method.
 */
cd.init = init;
cd.exec = _iconv_exec;
cd.close = _iconv_close;

/*
 *      Returns the core part
 */
return &cd;
}

```

Stateful converters

Because stateful converters need more information, they provide additional converter-dependent information. The following example of a stateful converter is a sample converter of IBM-930 to IBM-932 code set.

The **host.h** file contains the following structure:

```

typedef struct _LC_host_iconv_rec {
    _LC_core_iconv_t      core;
    iconv_t               curcd;
    iconv_t               sb_cd;
    iconv_t               db_cd;
    unsigned char         *cntl;
} _LC_host_iconv_t;

#include <stdlib.h>;
#include <sys/types.h>;
#include <iconv.h>;
#include "host.h"

/*
** The _iconv_exec subroutine to be invoked via cd->exec()
*/
static int      _iconv_exec(_LC_host_iconv_t *cd,
    unsigned char **inbuf, size_t *inbytesleft,
    unsigned char **outbuf, size_t *outbytesleft)
{
    unsigned char *in, *out;
    int          ret_value;

    if (!cd){
        errno = EBADF; return NULL;
    }

    if (!inbuf) {
        cd->curcd = cd->sb_cd;
        return ICONV_DONE;
    }

    do {

Input methods

For an application to run in the international environment for which globalization provides a base, input methods are needed. The Input Method is an application programming interface (API) that allows you to develop applications independent of a particular language, keyboard, or code set.

Each type of input method has the following features:

Input method type	Features
Keymaps	Set of input method keymaps (imkeymaps) that works with the input method and determines the supported locales.
Keysyms	Set of key symbols (keysyms) that the input method can handle.
Modifiers	Set of modifiers or states, each having a mask value, that the input method supports.

Related concepts:

“Input method support” on page 2

The input of characters becomes complicated for languages having large character sets. For example, in Chinese, Korean, and Japanese, where the number of characters is large, it is not possible to provide one-to-one key mapping for a keystroke to a character. However, a special input method enables the user to enter phonetic or stroke characters and have them converted into native-language characters.

“Reserved keysyms” on page 146

This section discusses the keysyms that are reserved by the input methods.

“AIXwindows checklist” on page 178

The remaining checklist items are specific to the AIXwindows systems.

Input method introduction

An input method is a set of functions that translates key strokes into character strings in the code set specified by your locale. Input method functions include locale-specific input processing and keyboard controls (for example, Ctrl, Alt, Shift, Lock, and Alt-Graphic). The input method allows various types of input, but only keyboard events are dealt with in this section.

Your locale determines which input method should be loaded, how the input method runs, and which devices are used. The input method then defines states and their outcome.

When the input method translates a keystroke into a character string, the translation process takes into account the keyboard and the code set you are using. You can write your own input method if you do not have a standard keyboard or if you customize your code set.

Many languages use a small set of symbols or letters to form words. To enter text with a keyboard, you press keys that correspond to symbols of the alphabet. When a character in your alphabet does not exist on the keyboard, you must press a combination of keys. Input methods provide algorithms that allow you to compose such characters.

Some languages use an ideographic writing system. They use a unique symbol, rather than a group of letters, to represent a word. For instance, the character sets used in mainland China, Japan, Korea, and Taiwan have more than 5,000 characters. Consequently, more than one byte must be used to represent a character. Moreover, a single keyboard cannot include all the required ideographic symbols. You need input methods that can compose multibyte characters.

The `/usr/lib/nls/loc` directory contains the input methods installed on your system. You can list the contents of this directory to determine which input methods are available to you. Input method file names have the format *Language_Territory.im*. For example, the `fr_BE.im` file is the input method file for the French language as used in Belgium.

Through a well-structured protocol, input methods allow applications to support different input without using locale-specific input processing.

In AIX, the input method is provided in the `aixterm`. When characters typed from the AIXwindows interface reach the server, the characters are in the form of key codes. A table provided in the client converts key codes into *keysyms*, a predefined set of codes. Any key code generated by a keyboard should have a keysym. These keysyms are maintained and allocated by the MIT X Consortium. The keysyms are passed to the client `aixterm` terminal emulator. In the `aixterm`, the input keysyms are converted into file codes by the input method and are then sent to the application. The X server is designed to work with the display adapter provided in the system hardware. The X server communicates with the X client through sockets. Thus, the server and the client can reside on different systems in a network, provided they can communicate with each other. The data from the keyboard enters the X server, and from the server, it is passed to the terminal emulator. The terminal emulator passes the data to the application. When data comes from applications to the display device, it passes through the terminal emulator by sockets to the server and from the server to the display device.

input method names

The set of input methods available depends on which locales have been installed and what input methods those locales provide. The name of the input method usually corresponds to the locale. For example, the Greek Input Method is named `el_GR`, which is the same as the locale for the Greek language spoken in Greece.

When there is more than one input method for a locale, any secondary input method is identified by a modifier that is part of the locale name. For example, the French locale, as spoken in Canada, has three input methods, the default and two alternative methods. The input method names are:

Input method name	Description
fr_CA	Default input method
fr_CA@im=alt	Alternative input method
fr_CA.im_64	64-bit input method

The **fr** portion of the locale represents the language name (French), and the **CA** represents the territory name (Canada). The **@im=alt** string is the modifier portion of the locale that is used to identify the alternative input method. All modifier strings are identified by the format **@im=Modifier**.

Because the input method is a loadable object module, a different object is required when running in the 64-bit environment. In the 64-bit environment, the input method library automatically appends **_64** to the name when searching for the input method. In the preceding example, the name of the input method would be **fr_CA.im_64**.

It is possible to name input methods without using the locale name. Because the **libIM** library does not restrict names to locale names, the calling application must ensure that the name passed to **libIM** can be found. However, applications should request only modifier strings of the form **@im=Modifier** and that the user's request be concatenated with the return string from the **setlocale (LC_CTYPE, NULL)** subroutine.

Input method areas

Complex input methods require direct dialog with users. For example, the Japanese Input Method may need to show a menu of candidate strings based on the phonetic matches of the keys that you enter.

The feedback of the key strokes appears in one or more areas on the display. The input method areas are as follows:

Status Text data and bitmaps can appear in the Status area. The Status area is an extension of the light-emitting diodes (LEDs) on the keyboard.

Pre-edit

Intermediate text appears in the Pre-edit area for languages that compose before the client handles the data.

A common feature of input methods is that you press a combination of keys to represent a single character or set of characters. This process of composing characters from keystrokes is called *pre-editing*.

Auxiliary

Menus and dialogs that allow you to customize the input method appear in the Auxiliary area. You can have multiple Auxiliary areas managed by the input method and independent of the client.

Management for input method areas is based on the division of responsibility between the application (or toolkit) and the input method. The divisions of responsibility are as follows:

- Applications are responsible for the size and position of the input method area.
- Input methods are responsible for the contents of the input area. The input method area cannot suggest a placement.

Input method command

An Input Method is a set of subroutines that translate key strokes into character strings in the code set specified by a locale. Input Method subroutines include logic for locale-specific input processing and keyboard controls (Ctrl, Alt, Shift, Lock, Alt Graphic).

The following command allows for the customizing of input method mapping for the use of input method subroutines:

keycomp

Compiles a keyboard mapping file into an input method keymap file.

Programming input methods

The input method is a programming interface that allows applications to run in an international environment that is provided through multicultural support.

The input method has the following characteristics:

- Localized input support (defined by locale)
- Multiple keyboard support
- Multibyte character-input processing

Note: Do not assume any particular physical keyboard is in use. Use an input method based on the locale setting to handle keyboard input.

Initialization

This section will discuss subroutines used to determine input methods.

You can use the `IMQueryLanguage` subroutine to determine if an input method is available without initializing it. An application (toolkit) initializes a locale-specific input method by calling the `IMInitialize` subroutine, which initializes a locale-specific input method editor (`IMED`). The subroutine uses the `LOCPATH` environment variable to search for the input method named by the `LANG` environment variable. The `LOCPATH` environment variable specifies a set of directory names used to search for input methods.

If the input method is found, the `IMInitialize` subroutine uses the `load` subroutine to load the input method and attach the `imkeymap` file. When the input method is accessed, an object of the type `IMFep` (input method front-end processor) is returned. The `IMFep` should be treated as an opaque structure.

Each `IMFep` inherits the locale's code set when the `IMInitialize` subroutine is called. Consequently, strings returned by the `IMFilter` and `IMLookupString` subroutines are in the locale's code set. Changing the locale after the `IMInitialize` subroutine is called does not affect the code set of the `IMFep`.

For each `IMFep`, the application can use the `IMCreate` subroutine to create one or more `IMObject` instances. The `IMObject` manages its own state and can manage several Input Method Areas (see "Input method areas" on page 121). How each `IMObject` defines input processing depends on the code set and keyboard associated with the locale. In the simplest case, a single `IMObject` is needed if the application is managing a single dialog with the user. The input method also supports other user interfaces where the application allows multiple dialogs with the user, and each dialog requires one `IMObject`.

The difference between an `IMFep` and `IMObject` is that the `IMFep` is a handle that binds the application to the code of the input method, while the `IMObject` is a handle that represents an instance of a state of an input device, such as a keyboard. The `IMFep` does not represent a state of the input method. Each `IMObject` is initialized to a specific input state and is changed according to the sequence of events it receives.

After the `IMObject` is created, the application can process key events. The application should pass key events to the `IMObject` using the `IMFilter` and `IMLookupString` subroutines. These subroutines are provided to isolate the internal processing of the `IMED` from the customized key event mapping process.

Input method management

This section discusses subroutines used for maintenance purposes.

The input method provides the following subroutines for maintenance purposes:

Input method	Description
IMInitialize	Initializes the standard input method for a specified language. Returns a handle to an IMED associated with the locale. The handle is an opaque structure of type IMFep.
.IMQueryLanguage	Checks whether the specified language is supported.
IMCreate	Creates one instance of a particular input method. This subroutine must be called before any key event processing is performed.
IMClose	Closes the input method.
IMDestroy	Destroys an instance of an input method.

Input method keymap management

The input method provides several subroutines to map key events to a string. The mapping is maintained in an **imkeymap** file located in the **LOCPATH** directory.

The subroutines used for mapping are as follows:

Subroutine	Description
IMInitializeKeymap	Initializes the imkeymap associated with a specified language.
IMFreeKeymap	Frees resources allocated by the IMInitializeKeymap subroutine.
IMAIXMapping	Translates a pair of key-symbol and state parameters to a string and returns a pointer to that string.
IMSimpleMapping	Translates a pair of key-symbol and state parameters to a string and returns a pointer to that string.

Key event processing

Input processing begins when you press keys on the keyboard.

The application must have created an **IMObject** before calling these functions:

Table 10. Key event processing

Function	Description
IMFilter	Asks the IMED to indicate if a key event is used internally. If the IMED is composing a localized string, it maps the key event to that string.
IMLookupString	Maps the key event to a localized string.
IMProcessAuxiliary	Notifies the input method of input for an auxiliary area.
IMIoctl	Performs a variety of control or query operations on the input method.

Callbacks

The IMED communicates directly with the user by using the Input Method-Callback (IM-CB) API to access the graphic-dependent functions (**callbacks**) provided by the application. The application attaches the callbacks, which perform output functions and query information, to the **IMObject** during initialization. The application still handles all the input.

The set of callback functions that the IMED uses to communicate with a user must be provided by the caller. See “Using callbacks” on page 125 for a discussion of the subroutines defined by the IM-CB API.

Input method structures

This section discusses major structure input methods.

The major structures used by the input method are as follows:

Structure	Description
IMFepRec	Contains the front end information
IMObjectRec	Contains the common part of input method objects
IMCallback	Registers callback subroutines to the IMFep
IMTextInfo	Contains information about the text area, primarily the pre-editing string
IMAuxInfo	Defines the contents of the auxiliary area and the type of processing requested
IMIndicatorInfo	Indicates the current value of the indicators
IMSTR	Designates strings that are not null-terminated
IMSTRATT	Designates strings that are not null-terminated and their attributes

Working with keyboard mapping

The following model shows how input methods are used by applications. Use this information to help you customize keyboard mapping.

Input processing is divided into three steps:

1. keycode/keystate(raw) - > keysym/modifier(new)

This step is application and environment-dependent. The application is responsible for mapping the raw key event into a keysym/modifier for input to the input method.

In the AIXwindows environment, the client uses the server's keysym table, **xmodmap**, which is installed at the server, to perform this step. The **xmodmap** defines the mapping of the Shift, Lock, and Alt-Graphic keys. The client uses the **xmodmap** as well as the Shift and Lock modifiers from the X event to determine the keysym/modifier represented by this event.

For example, if you press the **XK_a** keysym with a Shift modifier, the **xmodmap** maps it to the **XK_A** keysym. Because you used the Shift key to map the key code to a keysym, the application should mask the Shift modifier from the original X event. Consequently, the input to the input method would be the **XK_A** keysym and no modifier.

In another environment, if the device provides no additional information, the input method receives the **XK_a** keysym with the Shift modifier. The input method should perform the same mapping in both cases and return the letter A.

2. keysym/modifier(new) - > localized string

This step depends on the localized IMED and varies with each locale. It notifies the IMED that a key event occurred and to ask for an indication that their IMED uses the key event internally. This occurs when the application calls the **IMFilter** subroutine.

If the IMED indicates that the key event is used for internal processing, the application ignores the event. Because the IMED is the first to see the event, this step should be done before the application interprets the event. The IMED only uses key events that are essential.

If the IMED indicates the event is not used for internal processing, the application performs the next step.

3. keysym/modifier(new) - > customized string

This step occurs when the application calls the **IMLookupString** subroutine. The input method keymap (created by the **keycomp** command) defines the mapping for this phase. It is the last attempt to map the key event to a string and allows a user to customize the mapping.

If the keysym/modifier (new) combination is defined in the input method keymap (imkeymap), a string is returned. Otherwise, the key event is unknown to the input method.

Input method keymaps

The input method provides support for user-defined imkeymaps, allowing you to customize input method mapping. The input methods support imkeymaps for each locale. The file name for imkeymaps is similar to that of input methods, except that the suffix for imkeymap files is **.imkeymap** instead of **.im**.

This example uses the Italian input method to illustrate how you can customize your **imkeymap** file:

1. Copy the default **imkeymap** source file to your **\$HOME** directory by typing:

```
cd $HOME
cp /usr/lib/nls/loc/it_IT.IS08859-1.imkeymap.src .
```

2. Edit the **imkeymap** source file following the default file format by typing:

```
vi it_IT.IS08859-1.imkeymap.src
```

3. Compile the **imkeymap** source file by typing:

```
keycomp < it_IT.IS08859-1.imkeymap.src > it_IT.IS08859-1.imkeymap
```

4. Make sure the **LOCPATH** environment variable specifies **\$HOME** before **/usr/lib/nls/loc** by typing:

```
LOCPATH=$HOME:$LOCPATH
```

Note: All **setuid** and **setgid** programs ignore the **LOCPATH** environment variable.

Inbound and outbound mapping

The imkeymaps map a key symbol to a file code set string. The localized imkeymaps found in the **/usr/lib/nls/loc** library are defined to include mapping for all of the inbound keys.

The imkeymaps provide the following types of mapping:

Mapping type	Description
Inbound mapping	Mapping of a keysym or modifier that generates a target string encoded in the code set of the locale.
Outbound mapping	Mapping of a keysym or modifier that does not generate a target string included in the code set of the locale.

A special imkeymap, **/usr/lib/nls/loc/C@outbound.imkeymap**, defines outbound mapping for all keyboards made by this manufacturer and is primarily intended for use by aixterm. This imkeymap includes mapping of PF keys, cursor keys, and other special keys commonly used by applications. Globalized applications that use standard input and standard output should limit their dependency on outbound mapping, which does not vary on different keyboards. For example, the Alt-a is defined in the same way on all keyboards made by this manufacturer. Yet, the Alt-tilde is different depending on the keyboard used.

The aixterm bases its outbound mapping on the **C@outbound** imkeymap. Applications that require more mapping should modify the localized imkeymap source to include the necessary definitions.

Using callbacks

Applications that use input methods should provide callback functions so that the Input Method Editor (IMED) can communicate with the user. The type of input method you use determines whether or not callbacks are necessary. For example, the single-byte input method does not need callbacks, but the Japanese input method uses them extensively with the pre-edit facility. Pre-editing allows processing of characters before they are committed to the application.

When you use an input method, only the application can insert or delete pre-edit data and scroll the text. Consequently, the echo of the keystrokes is achieved by the application at the request of the input method logic through callbacks.

When you enter a keystroke, the application calls the **IMFilter** subroutine. Before returning, the input method can call the echoing callback function for inserting new keystrokes. After a character has been composed, the **IMFilter** subroutine returns it, and the keystrokes are deleted.

In several cases, the input method logic has to call back the client. Each of these is defined by a callback action. The client specifies which callback should be called for each action.

Types of callbacks are described as follows:

- Text drawing

The IMED uses text callbacks to draw any pre-editing text currently being composed. When the callbacks are needed, the application and the IMED share a single-line buffer, where the editing is performed. The IMED also provides cursor information that the callbacks then present to the user.

The text callbacks are as follows:

Callback subroutines	Description
IMTextDraw	Asks the application program to draw the text string
IMTextHide	Tells the application program to hide the text area
IMTextStart	Notifies the application program of the length of the pre-editing space
IMTextCursor	Asks the application program to move the text cursor

- Indicator (status)

The IMED uses indicator callbacks to request internal status. The **IMIoctl** subroutine works with the **IMQueryIndicatorString** command to retrieve the text string that provides the internal status.

Indicator callbacks are similar to text callbacks, except that instead of sharing a single-line buffer, a status value is used.

The indicator callbacks are as follows:

Callback subroutines	Description
IMIndicatorDraw	Tells the application program to draw the status indicator
IMIndicatorHide	Tells the application program to hide the status indicator
IMBeep	Tells the application program to emit a beep sound

- Auxiliary

The IMED uses auxiliary callbacks to request complex dialogs with the user. Consequently, these callbacks are more sophisticated than text or indicator callbacks.

The auxiliary callbacks are as follows:

Callback subroutines	Description
IMAuxCreate	Tells the application program to create an auxiliary area
IMAuxDraw	Tells the application program to draw an auxiliary area
IMAuxHide	Tells the application program to hide an auxiliary area
IMAuxDestroy	Tells the application program to destroy an auxiliary area

The **IMAuxInfo** structure defines the dialog needed by the IMED.

The contents of the auxiliary area are defined by the **IMAuxInfo** structure, found in the **/usr/include/im.h** library.

Subroutine contents	Description
IMTitle	Defines the title of the auxiliary area. This is a multibyte string. If <code>title.len</code> is 0, no title displays.
IMMessage	<p>Defines a list of messages to be presented. From the applications perspective, the IMMessage structure should be treated as informative, output-only text. However, some input methods use the IMMessage structure to conduct a dialog with the user in which the key events received by way of the IMFilter or IMLookupString subroutine are treated as input to the input method. In such cases, the input method may treat the IMMessage structure as either a selectable list or a prompt area. In either case, the application displays only the message contents.</p> <p>The IMProcessAuxiliary subroutine need not be called if the IMSelection structure contains no IMPanel structures and the IMButton field is null.</p> <p>The <code>message.nline</code> indicates the number of messages contained in the IMMessage structure. Each message is assumed to be a single line. Control characters, such as <code>\t</code>, are not recognized. The text of each message is defined by the IMSTRATT structure, which consists of both a multibyte string and an attribute string. Each attribute is mapped one-to-one for each byte in the text string.</p> <p>If <code>message.cursor</code> is True, then the IMMessage structure defines a text cursor at location <code>message.cur_row</code>, <code>message.cur_col</code>. The <code>message.cur_col</code> field is defined in terms of bytes. The <code>message.maxwidth</code> field contains the maximum width of all text messages defined in terms of columns.</p>
IMButton	<p>Indicates the possible buttons that can be presented to a user. The IMButton field tells the application which user interface controls should be provided for the end user. The button member is of type <code>int</code> and may contain the following masks:</p> <p>IM_OK Present the OK button.</p> <p>IM_CANCEL Present the CANCEL button.</p> <p>IM_ENTER Present the ENTER button.</p> <p>IM_RETRY Present the RETRY button.</p> <p>IM_ABORT Present the ABORT button.</p> <p>IM_YES Present the YES button.</p> <p>IM_NO Present the NO button.</p> <p>IM_HELP Present the HELP button.</p> <p>IM_PREV Present the PREV button.</p> <p>IM_NEXT Present the NEXT button.</p> <p>The application should use the IMProcessAuxiliary subroutine to communicate the button selection.</p>

Subroutine contents	Description
IMSelection	<p>Defines a list of items, such as ideographs, that an end user can select. This structure is used when the input method wants to display a large number of items but does not want to control how the list is presented to the user.</p> <p>The IMSelection structure is defined as a list of IMPanel structures. Not all applications support IMSelection structures inside the IMAuxInfo structure. Applications that do support IMSelection structures should perform the IM_SupportSelection operation using the IMIoctl subroutine immediately after creation of the IMObject. In addition, not all applications support multiple IMPanel structures. Therefore, the <code>panel_row</code> and <code>panel_col</code> fields are restricted to a setting of 1 by all input methods.</p> <p>Each IMPanel structure consists of a list of IMItem fields that should be treated as a two-dimensional, row/column list whose dimensions are defined as <code>item_row</code> times <code>item_col</code>. If <code>item_col</code> is 1, there is only one column. The size of the IMPanel structure is defined in terms of bytes. Each item within the IMPanel structure is less than or equal to <code>panel->maxwidth</code>.</p> <p>The application should use the IMProcessAuxiliary subroutine to communicate one or more user selections. The IM_SELECTED value indicates which item is selected. The IM_CANCEL value indicates that the user wants to terminate the auxiliary dialog.</p>
hint	Used by the input method to provide information about the context of the IMAuxInfo structure. A value of IM_AtTheEvent indicates that the IMAuxInfo structure is associated with the last event passed to the input method by either the IMFilter or IMLookupString subroutine. Other hints are used to distinguish when multiple IMAuxInfo structures are being displayed.
status	Used by the input method for internal processing. This field should not be used by applications.
	Each IMAuxInfo structure is independent of the others. The method used for displaying the members is determined by the caller of the input method. The IMAuxInfo structure is used by the IMAuxDraw callback.

Related concepts:

“Kanji Pre-edit” on page 135

When operating in Romaji-To-Kana conversion mode, you must follow two steps to produce Kanji characters. First, the user enters Hiragana characters by typing their Romaji phonetic characters. In this step, you produce a Hiragana character by typing 1 to 3 Romaji alphabetic keys that compose the phonetic sound of the Hiragana character. Second, convert the Hiragana characters to Kanji characters by pressing the Henkan key. Many Kanji characters may be associated with a single phonetic phrase. The Henkan key displays the most likely Kanji candidates. Repeated pressing of the Henkan key displays all the additional candidates.

Initializing callbacks

All callbacks must be identified when you call the **IMCreate** subroutine. The **IMCallback** structure contains the address for each callback function. The caller of the **IMCreate** subroutine must initialize the **IMCallback** structure with the addresses.

The callback functions can be called before the **IMCreate** subroutine returns control to the caller. Usually, the **IMTextStart** callback is called to identify the size of the pre-edit buffer.

Bidirectional input method

The bidirectional input method (BIM) is similar to the single-byte input method except that it is customized to process the Arabic, Hebrew, and Urdu keyboards. BIM also links the Hebrew and Arabic states to the Latin states. The Alt+Right Shift keys allow the user to toggle between the Arabic/Hebrew/Urdu and Latin language layers. The use of these keys is derived from BIM.

The features of BIM are as follows:

- Supports Arabic, Hebrew, and Latin states
- Supports the ISO8859-6, ISO8859-8, IBM-1046, IBM-856, and Unicode UTF-8 code sets
- Performs diacritical composing

Keymaps

This section discusses keymaps supported on Bidirectional Input Method (BIM).

The following keymaps are supported on BIM:

- ar_AA.ISO8859-6.imkeymap
- ar_AA@alt.ISO8859-6.imkeymap
- Ar_AA.IBM-1046.imkeymap
- Ar_AA@alt.IBM-1046.imkeymap
- iw_IL.ISO8859-8.imkeymap
- iw_IL@alt.ISO8859-8.imkeymap
- Iw_IL.IBM-856.imkeymap
- Iw_IL@alt.IBM-856.imkeymap

Key settings

This section discusses key settings supported on Bidirectional Input Method (BIM).

The following key settings are supported on BIM:

Key settings	Description
scr-rev()	Reverses the screen orientation and sets the keyboard layer to the default language of the new orientation.
ltr-lang()	Enables the Latin keyboard layer.
rtl-lang()	Enables the Arabic/Hebrew keyboard layer.
col-mod()	Enables the column heading adjustment, which handles each word as a separate column.
auto-push()	Toggles the Autopush mode, which handles mixed left-to-right and right-to-left text. When you enable the Autopush mode, reversed segments are automatically initiated and terminated according to the entered character or the selected language layer. Thus, you are relieved of manually invoking the Push function.
chg-push()	Toggles the Push mode. This mode causes the cursor to remain in its position and pushes the typed characters in the direction opposed to the field direction.
shp-in()	Shapes Arabic characters in their initial forms.
shp-is()	Shapes Arabic characters in their isolated forms.
shp-p()	Shapes Arabic characters in their passthru forms.
shp-asd()	Shapes Arabic characters in their automatic forms.
shp-m()	Shapes Arabic characters in their middle forms.
shp-f()	Shapes Arabic characters in their final forms.

Modifiers

This section discusses modifiers supported on Bidirectional Input Method (BIM).

The following modifiers are supported on BIM:

Modifier	Description
ShiftMask	0x01
LockMask	0x02
ControlMask	0x04
Mod1Mask (Left-Alt)	0x08
Mod2Mask (Right-Alt)	0x10

Cyrillic input method (CIM)

The Cyrillic input method (CIM) is similar to the single-byte input method, except that it is customized for processing the Cyrillic keyboard.

The features of CIM are as follows:

- Supports Cyrillic and Latin states. You can toggle between the two states by pressing the Alt key and the Left or Right Shift key simultaneously.

Note: The Alt-Graphic (Right Alt) key can be used to generate additional characters within each keyboard layer.

- For the Russian and Bulgarian locales, both 101-key and 102-key keyboard drivers are supported.
- Supports the ISO8859-5 code set.

keymap

This section discusses keymaps supported on Cyrillic input method (CIM).

The following keymaps are supported on the CIM:

- bg_BG.ISO8859-5.imkeymap
- mk_MK.ISO8859-5.imkeymap
- sr_SP.ISO8859-5.imkeymap
- ru_RU.ISO8859-5.imkeymap
- be-BY.ISO8859-5.imkeymap
- uk-UA.ISO8859-5.imkeymap

Keysyms

The CIM uses the keysyms in the `XK_CYRILLIC`, `XK_LATIN1`, and `XK_MISCELLANY` groups.

The following reserved keysyms are unique to the input method of this system:

Keysym	Hexadecimal representation
<code>XK_dead_acute</code>	0x180000b4
<code>XK_dead_grave</code>	0x18000060
<code>XK_dead_circumflex</code>	0x1800005e
<code>XK_dead_diaeresis</code>	0x180000a8
<code>XK_dead_tilde</code>	0x1800007e
<code>XK_dead_caron</code>	0x180001b7
<code>XK_dead_breve</code>	0x180001a2
<code>XK_dead_doubleacute</code>	0x180001bd
<code>XK_dead_degree</code>	0x180000b0
<code>XK_dead_abovedot</code>	0x180001ff
<code>XK_dead_macron</code>	0x180000af
<code>XK_dead_cedilla</code>	0x180000b8
<code>XK_dead_ogonek</code>	0x180001b2
<code>XK_dead_accentdiaeresis</code>	0x180007ae

Modifiers

This section discusses modifiers supported on Cyrillic Input Method (CIM).

The following modifiers are supported on CIM:

Modifier	Hexadecimal representation
ShiftMask	0x01
LockMask	0x02
ControlMask	0x04
Mod1Mask (Left-Alt)	0x08
Mod2Mask (Right-Alt)	0x10

The following internal modifier is supported on CIM:

Modifier	Hexadecimal representation
Cyrillic Layer	0x20

Greek input method (GIM)

The Greek input method (GIM) is similar to the single-byte input method (SIM), but handles both Latin and Greek character sets, by providing two layers or states of keyboard mappings, which correspond to the two character sets.

The keyboard is initially in the Latin input state. However, if the left-shift key is pressed while the left-alt key is held down, the keyboard is put in the Greek input state. The keyboard can be returned to the Latin state by pressing the right-shift key, while the left-alt key is held down. These are locking shift keys, because the state is locked when they are pressed.

While in the Greek state, the input method recognizes the following diacritical characters and valid subsequent characters for diacritical composing as shown in the following table:

Table 11. Greek Composing Characters

Keysym	Valid Composing Characters
dead_acute	uppercase and lowercase: alpha, epsilon, eta, iota, omicron, upsilon, omega
dead_diaeresis	uppercase and lowercase: iota, upsilon
dead_accentdiaeresis	lowercase only: iota, upsilon

In the Latin state, there are no composing diacriticals, and the keys shown in the table above are treated as simple graphic characters.

The Greek and Single-Byte Input Methods also differ in their handling of illegal diacritical composing sequences. In such cases, the GIM beeps and returns no characters. The SIM does not beep and returns both the diacritical character and a graphic character associated with the invalid key.

Note: The Alt-Graphic (right-alt) key can be used to generate additional characters within each keyboard state.

Keymap

This section discusses keymaps supported on Greek Input Method (GIM).

The following keymap is supported on GIM:

- `eL_GR.ISO8859-7.imkeymap`

Keysyms

The GIM uses the keysyms in the `XK_LATIN1`, `XK_GREEK`, and `XK_MISCELLANY` groups.

The following reserved keysyms are unique to the input method of this system.

Keysym	Hexadecimal representation
XK_dead_acute	0x180000b4
XK_dead_grave	0x18000060
XK_dead_circumflex	0x1800005e
XK_dead_diaeresis	0x180000a8
XK_dead_tilde	0x1800007e
XK_dead_caron	0x180001b7
XK_dead_breve	0x180001a2
XK_dead_doubleacute	0x180001bd
XK_dead_degree	0x180000b0
XK_dead_abovedot	0x180001ff
XK_dead_macron	0x180000af
XK_dead_cedilla	0x180000b8
XK_dead_ogonek	0x180001b2
XK_dead_accentdiaeresis	0x180007ae

Modifiers

This section discusses modifiers supported on Greek input method (GIM).

The following modifiers are supported on GIM:

Modifiers	Hexadecimal representation
ShiftMask	0x01
LockMask	0x02
ControlMask	0x04
Mod1Mask (Left-Alt)	0x08
Mod2Mask (Right-Alt)	0x10

The following internal modifier is supported on GIM:

Modifiers	Hexadecimal representation
Greek Layer	0x20

Japanese input method (JIM)

This section discusses the Japanese input method (JIM).

The Japanese input method (JIM) include the following features:

- Supports Romaji to Kana character conversion (RKC).
- Supports Kana to Kanji character conversion (KKC).
- Includes Hankaku (half-width) and Zenkaku (full-width) character input.
- Provides system and user dictionary lookup.
- Provides run-time registration of a word to the user dictionary.

- Requires Callback functions to support:
 - Status and Pre-edit drawing
 - All candidate menus
 - JIS Kutan number input and IBM Kanji number input
- Supports IBM-943, IBM-932 and IBM-eucJP code sets. For internal processing, the JIM uses the IBM-942 code set. However, the JIM supports any code set, such as IBM-eucJP, that can be converted from IBM-932.
- Located in the /usr/lib/nls/loc/JP.im file. All other localized input methods are aliases to this file.

Katakana and Hiragana consist of approximately 50 characters each and form the set of phonetic characters referred to as Kana. All of the sounds in the Japanese language can be represented in Kana.

Kanji is a set of ideographs. A simple concept can be represented by a single Kanji character, while more complicated meanings can be formed with strings of Kanji characters. Several thousand Kanji characters exist.

The Japanese also use the Roman alphabet. Called Romaji, the Roman alphabet consists of 26 characters. It is used mostly in technical and professional environments to represent technical vocabulary that does not exist in Japanese. A typical sentence is usually a mixture of Katakana, Hiragana, Kanji, Romaji, numbers, and other characters.

Japanese character processing

The Japanese Industrial Standard (JIS) specifies about 7000 Kanji characters processed by computer systems. Japanese products made by this manufacturer support all of the standard characters, as well as others.

Input of the characters is accomplished through the following:

- Kana-to-Kanji conversion (KKC)
- Romaji-to-Kana conversion (RKC)

Table 12. Special Japanese Keys

Key function	Key name	Description of function
KKC Non-conversion key	muhenkan	Leaves Kana characters as is.
KKC Conversion key	henkan	Converts Kana to Kanji.
KKC All Candidates key	zenkouho	Shows all possible Kanji representatives.
RKC Romaji Mode key	romaji	Toggles RKC on and off.
Hiragana Shift key	hiragana	Becomes Hiragana shift state.
Katakana Shift key	katakana	Becomes Katakana shift state.
Romaji Shift key	eisu	Becomes Romaji shift state.

Note: Shift states are maintained until you press another shift key. The initial state is Romaji.

Kana-to-Kanji conversion (KKC) technology

The Japanese input method's (JIM) KKC technology is based on the fact that every Kanji character or set of Kanji characters has a phonetic sound or sounds that can be expressed by Katakana or Hiragana characters.

It is much easier to input Hiragana or Katakana characters than Kanji characters. The JIM analyzes the phonetic values of the Hiragana and Katakana characters to determine the best Kanji-character equivalent. Such phonetic analysis depends on the dictionary and tables provided to the JIM.

Input modes

This section discusses the modes in the Japanese Input Method.

The Japanese input method's (JIM) has the following modes that can be used to control the input processing:

- **Keyboard Mapping**
Allows invocation of alphanumeric, Katakana, or Hiragana modes.
- **Character Size**
Inputs in Zenkaku (full-width) or Hankaku (half-width) mode.
- **RKC off/on**
Inputs Kana directly or invokes the pre-edit composing mode to input Kana with a combination of alphabetic characters. The pre-editing facility allows processing of characters before they are committed to the application.

When the keyboard-mapping mode is alphanumeric and the character size mode is Hankaku, the JIM maps keys to Romaji characters. This mode combination is known as the "English" mode. Pre-editing is not needed in English mode and cannot be invoked regardless of the RKC mode setting. The other mode combinations may initiate pre-editing and characters generated in these modes are not ASCII.

The following keys are used to perform Kana-to-Kanji conversion by the JIM.

Keysym	Keyboard mapping
Katakana	Katakana shift
Eisu_toggle	Alphanumeric shift
Hiragana	Hiragana shift

Keysym	Character size
Zenkaku_Hankaku	Full-width or Half-width toggle
Hankaku	Half-width
Zenkaku	Full-width

Keysym	RKC on/off
Alt-Hiragana	Enables/Disables Romaji-to-Kana conversion
Romaji	*The same effect

* Keysyms unique to the manufacturer

The following keys are also used when the JIM is pre-editing a Kanji string.

Keysym	Kanji pre-edit
Muhenkan	Non-conversion - commit Kana
Henkan	Conversion - get next candidate
Kanji	Same as Henkan
BunsetsuYomi	*Moves back a phrase
MaeKouko	*Moves to previous candidate
LeftDouble	*Moves cursor two characters left
RightDouble	*Moves cursor two characters right
ErInput	*Discards the current pre-edit string

Keysym	Auxiliary pre-edit
Alt-Henkan	All candidates
Touroku	Run-time registration
ZenKouho	*All candidates (the same effect)
KanjiBangou	*Kanji Number Input
HenkanMenu	*Changes conversion mode

* Keysyms unique to the manufacturer

Keyboard mapping

The following keyboard mapping states are possible: Alphanumeric (Romaji), Katakana, and Hiragana. Each state is invoked by a keysym that acts as a locking shift key. The keysyms are Katakana, Eisu_toggle, and Hiragana shift.

When one of these keysyms is pressed, keyboard mapping enters the state associated with the key. This state is maintained until one of the other keysyms is pressed. The initial shift state is Eisu_toggle, which can be changed by customization.

When you invoke the Hiragana or Katakana state, each key is mapped to a phonetic character within the respective character set. For example, if you press *q*, a Hiragana character pronounced "ta" is produced during Hiragana shift state, a Katakana character pronounced "ta" is produced during Katakana shift state, or a Romaji *q* is produced during Eisu_toggle shift state. On Japanese IBM keyboards, the tops of keys show all three symbols.

Also, when keyboard mapping is in Hiragana state, the input method is automatically put into a composing pre-editing mode where each Hiragana character can be converted into a Kanji character.

Some keys have two Hiragana or Katakana characters assigned. For example, the 7 key has large and small Hiragana characters both having the pronunciation "ya". These characters are not uppercase and lowercase equivalents of each other because Kanji, Hiragana, and Katakana do not have uppercase and lowercase. The small characters are used to express special phonetic sounds. These characters can be distinguished by using the shift key.

Character size

A subset of the Japanese character set is represented in both full-width and half-width. Kanji ideographic characters are usually full-width. The phonetic and ASCII characters have both full-width and half-width representations. The user controls character size by pressing the Zenkaku_Henkaku keysym, which toggles between full-width and half-width.

Romaji-To-Kana conversion (RKC)

For users familiar with alphanumeric keyboards, it is easier to type the phonetic sounds rather than the Hiragana or Katakana characters. The JIM provides Romaji-to-Kana conversion (RKC), allowing the user to type in the phonetic sounds of Hiragana or Katakana characters on an alphanumeric keyboard.

Kanji Pre-edit

When operating in Romaji-To-Kana conversion mode, you must follow two steps to produce Kanji characters. First, the user enters Hiragana characters by typing their Romaji phonetic characters. In this step, you produce a Hiragana character by typing 1 to 3 Romaji alphabetic keys that compose the phonetic sound of the Hiragana character. Second, convert the Hiragana characters to Kanji characters by pressing the Henkan key. Many Kanji characters may be associated with a single phonetic phrase. The Henkan key displays the most likely Kanji candidates. Repeated pressing of the Henkan key displays all the additional candidates.

For example, when you enter the Kanji characters for the phonetic sound "k-a-n-j-i", you must do two things:

1. Set the keyboard mapping to the Hiragana state.
2. Enable Romaji-to-Kana mapping by pressing the Alt-Hiragana key. This action invokes the alphanumeric keyboard.

You can now press the keys that spell "kanji". As each phonetic sound is completed, a Hiragana character displays.

The Hiragana character is displayed with visual feedback to indicate that the JIM is composing in a pre-edit state. The character is underlined and shown in reverse video. This feedback facility is known as a *callback*.

To convert the Hiragana character within the pre-edit string to a Kanji character, press the Henkan key. The most likely candidate associated with the phonetic Hiragana sound displays. Pressing this key repeatedly shows other candidates.

During the composition process, the pre-edit string is partitioned into segments that can be considered Kanji words. After a string of kana characters is converted into a candidate, it is treated as one of these convertible segments. While the pre-edit string is displayed, the JIM uses the cursor key and other keys to manipulate the string.

To commit the pre-edit string to the program, the user presses the Enter key. In this case, the Enter key code itself is not sent to the program, only the string.

The Muhenkan keysym can also be used to turn off pre-edit and commit the Hiragana or Katakana character directly to the program.

The following table depicts the shift state transition and the interaction of the RKC mode key with the shift states.

Character Encoding	Code Points	Description	Count
000xxxxx	00–1F	Controls	32
00100000	20	Space	1
0xxxxxxx	21–7E	7-bit ASCII	94
01111111	7F	Delete	1
10000000	80	Undefined	1
100xxxxx 01xxxxxx	[81–9F] [40–7E]	Double byte	1953
100xxxxx 1xxxxxxx	[81–9F] [80–FC]	Double byte	3844
10100000	A0	Undefined	1
1xxxxxxx	A1–DF	8-bit single byte	63
111xxxxx 01xxxxxx	[E0–FC] [40–7E]	Double byte	1827
111xxxxx 1xxxxxxx	[E0–FC] [80–FC]	Double byte	3596
11111101	FD	Undefined	1
11111110	FE	Undefined	1
11111111	FF	All ones	1

The JIM has the following types of auxiliary areas:

- All Candidates menu
- Kanji Number Input dialog
- Conversion Mode menu

- Runtime Registration dialog

A Kana-to-Kanji conversion operation on a string of Hiragana or Katakana characters can yield from one to a hundred Kanji candidates. At worst, you would have to press the conversion key more than a hundred times to get the correct Kanji character.

In such cases, it is more convenient to find the correct character by requesting the All Candidates menu with the ZenKouho or the Alt-Henkan keysym. This menu displays if the current target (a Kanji word that the cursor is pointing to in the pre-edit area) has several alternative candidates associated with it. The menu contains multiple candidates for selection. The All Candidates menu disappears when the Reset keysym is pressed, the Enter key is pressed, or a candidate is selected.

A Kanji Number Input dialog prompts the user to select the Kanji character by entering 3 to 5 digits. The digits represent the code of the character. Online dictionaries allow a user to search for the code. The ordering formats for these dictionaries vary. For example, one dictionary lists codes by phonetic sound. Another dictionary orders codes by the number of strokes used to compose the character. The KanjiBangou keysym invokes this menu. The menu is terminated with either the Reset or Return keysym.

The HenkanMenu keysym invokes the Conversion Mode menu. Four items are displayed for selection. The most important items are the word-conversion mode and phrase-conversion mode. Make a selection by choosing a number and pressing the Return keysym. This menu is terminated when either a selection is made or the Reset keysym is pressed.

A run-time registration dialog prompts the user to enter a Kana string and a Kanji string for registering the mapping of the strings in the user dictionary. After the pair is registered, the JIM can use it as a conversion candidate. The menu is terminated with the Escape or Reset keysym.

The presentation of menus depends on the interface environment in which the JIM is operating. For example, some interfaces support scrolling menus that use the Page Down and Page Up keys.

Related concepts:

“Using callbacks” on page 125

Applications that use input methods should provide callback functions so that the Input Method Editor (IMED) can communicate with the user. The type of input method you use determines whether or not callbacks are necessary. For example, the single-byte input method does not need callbacks, but the Japanese input method uses them extensively with the pre-edit facility. Pre-editing allows processing of characters before they are committed to the application.

Keymaps

This section discusses keymaps supported by the Japanese Input Method (JIM).

The following keymaps are supported by the JIM:

- ja_JP.IBM-eucJP.imkeymap
- Ja_JP.IBM-932.imkeymap
- Ja_JP.IBM-943.imkeymap

Keysyms

The JIM uses the keysyms in the `XK_KATAKANA`, `XK_LATIN1`, and `XK_MISCELLANY` groups.

The following reserved keysyms are unique to the input method of this system:

Keysym	Hexadecimal representation	Description
XK_BunsetsuYomi	0x1800ff05	Back a phrase to Yomi
XK_MaeKouho	0x1800ff04	Previous candidate
XK_ZenKouho	0x1800ff01	All candidates
XK_KanjiBangou	0x1800ff02	Kanji number input
XK_HenkanMenu	0x1800ff03	Changes conversion mode
XK_LeftDouble	0x1800ff06	Moves cursor two characters left
XK_RightDouble	0x1800ff07	Moves cursor two characters right
XK_LeftPhrase	0x1800ff08	Reserved for future use
XK_RightPhrase	0x1800ff09	Reserved for future use
XK_ErInput	0x1800ff0a	Discards the current pre-edit string
XK_Resetreset	0x1800ff0b	Reset

Keysym	Description
XK_Kanji	Convert Hiragana to Kanji.
XK_Muhenkan	Cancel conversion.
XK_Romaji	Puts JIM in Romaji input mode.
XK_Hiragana	Puts JIM in Hiragana input mode.
XK_Katakana	Puts JIM in Katakana input mode.
XK_Zenkaku_Hankaku	Toggles between full-width and half-width character input mode.
XK_Touroku	Registers a word to the user dictionary.
XK_Eisu_toggle	Puts JIM in alphanumeric input mode.

Modifiers

This section discusses modifiers supported on Japanese input method (JIM).

The following modifiers are supported by the JIM:

Modifier	Hexadecimal representation
ShiftMask	0x01
LockMask	0x02
ControlMask	0x04
Mod1Mask (Left-Alt)	0x08
Mod2Mask (Right-Alt)	0x10

The following internal modifiers are supported by the JIM:

Modifier	Hexadecimal representation
Kana	0x20
Romaji	0x40

Korean input method (KIM)

This section discusses the Korean input method (KIM).

The Korean EUC code set consists of the following main character groups:

- ASCII (English)
- Hangul (Korean characters)

The Hangul code set includes Hangul and Hanja (Chinese) characters. One Hangul character can comprise several consonants and vowels. However, most Hangul words can be expressed in Hanja. Each Hanja character has its own meaning and is thus more specific than Hangul.

The current Korean standard code set, KSC5601, contains 8224 Hangul, Hanja, and special characters. To comply with the Korean standard Extended UNIX Code (EUC), this code set is assigned to CS1 of the EUC.

Input of characters can be accomplished through the following:

- ASCII

ASCII mode is used for entering English characters.

- Hangul

The XK_Hangul key invokes Hangul mode, which must be used to enter Hangul characters. After Hangul mode is invoked, the KIM composes incoming consonants and vowels according to Hangul composition rules. A Hangul character is composed of a consonant followed by a vowel. A final consonant is optional. If incoming characters violate the construct rule, a warning beep is sounded.

There are about 1500 special characters in the standard code set. These characters must be entered with the Code Input function of the KIM. The Code Input key invokes the Code Input function. When the Code Input function is invoked, the code point for a desired character can be entered in the Code Input auxiliary window.

- Hanja

The XK_Hangul_Hanja key invokes the Hanja mode. Hanja characters can only be converted from the appropriate Hangul character. There are two modes for Hangul-to-Hanja Conversion (HHC): single-candidate and multi-candidate. In this context, a candidate is a selection of possible character choices.

In single-candidate mode, the candidates display one by one on the command line. In multi-candidate mode, up to ten candidates at a time display in an auxiliary window.

When the Hanja conversion mode is employed, any Hangul character can be converted into Hanja when the Conversion key is pressed. Similarly, any Hanja word can be converted to the appropriate Hangul word.

Hanja can also be entered with the Code Input function in the same manner used for entering Hangul.

To allow for these conversions, the following special keys appear on the 106-key Korean keyboard.

Table 13. Special Korean Keys

Key Function	Keysym	Description of Function
Hangul/English toggle key	XK_Hangul	Toggles between Hangul and English modes
Hanja toggle key	XK_Hangul_Hanja	Toggles Hanja mode on and off
Code Input key	XK_Hangul_Codeinput	Invokes the Code Input function, which allows characters to be entered by their code points
HHC All-Candidate key	XK_Hangul_MultipleCandidate	Invokes the multi-candidate mode
HHC Conversion key	XK_Hangul_Conversion	Invokes the single-candidate mode and also scrolls forward through the candidates in both single-candidate and multi-candidate modes
HHC Non-Conversion key	XK_Hangul_NonConversion	Scrolls backwards through the candidates

Latvian input method (LVIM)

The Latvian input method (LVIM) is similar to the single-byte input method (SIM), except that it is customized for processing the Latvian keyboard.

The features of the LVIM are as follows:

- Supports QWERTY and Ergonomic groups, as two main groups. There are two more supplementary groups which are accessible through dead keys from both main groups:
 - Pressing the left-alt key and left-shift key simultaneously, puts keyboard in the Ergonomic group.
 - Pressing the left-alt key and right-shift key simultaneously, puts keyboard in the QWERTY group.
- Supports the IBM-921 code set.

Keymap

This section discusses keymap support by the Latvian Input Method LVIM).

The following keymap is supported by the LVIM:

- Lv_LV.IBM-921.imkeymap

Lithuanian input method (LTIM)

The Lithuanian input method (LTIM) is similar to the single-byte input method (SIM), except that it is customized for processing the Lithuanian keyboard.

The features of LTIM are as follows:

- Supports Programmed and Lithuanian groups, as two main groups. There are two more supplementary groups which are accessible through dead keys from both main groups.
 - Pressing the left-alt key and left-shift key simultaneously, puts keyboard in the Lithuanian group.
 - Pressing the left-alt key and right-shift key simultaneously, puts keyboard in the Programmed group.
- Supports the IBM-921 code set.

Keymap

This section discusses keymap support by the Lithuanian Input Method LTIM).

The following keymap is supported by the LTIM:

- Lt_LT.IBM-921.imkeymap

Thai input method (THIM)

The Thai input method is similar to the single-byte input method (SIM), except that it is customized for processing the Thai language.

Specifically, it is designed to prevent entry of combinations of Thai characters (consonants, upper/lower vowels, tone marks) that are not valid in the Thai language. The features of the THIM are as follows:

- Supports Latin and Thai groups, as the two main groups on the keyboard.
 - Pressing the left-alt key and left-shift key puts the keyboard in the Thai group.
 - Pressing the left-alt key and right-shift key puts the keyboard in the Latin group.
- Supports the TIS-620 code set.

keymap

This section discusses keymap support by the Thai Input Method THIM).

The following keymap is supported by the THIM:

- th_TH.TIS-620.imkeymap

Vietnamese input method (VNIM)

The Vietnamese input method (VNIM) is similar to the single-byte input method (SIM), except that it is customized for processing the Vietnamese language.

Specifically, it is designed to prevent entry of combinations of Vietnamese characters (tone marks), that are not valid in the Vietnamese language. The Vietnamese tone-mark characters can only be entered immediately after one of the Vietnamese vowels (a, e, i, o, u, y, a-circumflex, e-circumflex, o-circumflex, a-breve, o-horn, or u-horn).

The VNIM supports a single keyboard layer, including some pre-composed characters and Vietnamese tone marks.

The VNIM supports the IBM-1129 code set.

keymap

This section discusses keymap support by the Vietnamese Input Method (VNIM).

The following keymap is supported by the VNIM:

- Vi_VN.IBM-1129.imkeymap

Simplified Chinese input method (ZIM-UCS)

This section discusses the Simplified Chinese input method (ZIM-UCS).

The UCS-2 code set consists of almost all character groups. The following character groups exist for the ZH_CN locale:

- ASCII (English)
- Glyphs
- Chinese, Japanese, and Korean (CJK) Characters (unification characters)

The CJK character set contains 20,992 character positions, but only 20,902 positions are assigned to Chinese characters.

The pronunciation of simplified Chinese is represented by phonetic symbols called Bopomofo. There are 25 phonetic symbols. Simplified Chinese characters are represented by one to three phonetic symbols.

ZIM-UCS features the following characteristics:

- The following commonly used input methods exist:

Intelligent ABC

An input method based on the phonetic representation of Chinese characters.

Pin Yin Input Method

An input method based on the phonetic representation of Chinese characters. A Chinese character is divided into one or several phonemes according to its pronunciation.

Wu Bi (Five Strike) Input Method

An input method based on the grapheme representation of Chinese characters. According to the WuBi grapheme input method, Chinese characters are classified into three levels: stroke, radical and single-character.

Zheng Ma

An input method based on the grapheme representation of Chinese word.

Biao Xing Ma Input Method

An input method in which a Chinese character is divided into several components, or *radicals*. When coding a character, these radicals are presented with the corresponding English letters.

Internal Code Input Method

An input method in accordance with the code table defined in GB18030 (Chinese Internal Code Specification) and UCS-2 (Unicode System Version 2).

- Half-width and full-width character input. Supports ASCII characters in both single-byte and multibyte modes.
- Auxiliary window to support all the candidate lists. For example, Intelligent ABC generate a list of possible characters that contain the same sound symbols (*radicals*). Users select the desired characters by pressing the conversion key.
- Over-the-spot pre-editing drawing area. Allows entry of radicals in reverse video area that temporarily covers the text line. The complete character is sent to the editor by pressing the conversion key.

The UCS-ZIM files are in the `/usr/lib/nls/loc` directory.

The UCS-ZIM keymap is in the `/usr/lib/nls/loc/ZH_CN.UTF-8.imkeymap` directory.

Chinese (CJK) character processing

UCS-ZIM is invoked by pressing one of the input method keys. Each radical or phonetic symbol is assigned to a key. The user inputs radicals or phonetic symbols to an over-the-spot pre-editing area. For internal code input method, a character is generated when the last key is pressed. Other input methods generate a list of candidates that display in a window. The user chooses the desired character by selecting the candidate number. Invalid input generates a beep and an error message. The glyphs can be input using the ABC input method.

Single-byte input method (SIM)

The SIM is the standard that supports most of the locales. SIM is a mapping function that supports simple composing defined on workstation keyboards associated with single-byte locales. SIM supports any keyboard, code set, and language that the `keycomp` command can describe. You can customize SIM using imkeymaps. The coded strings returned by the input method depend on the imkeymap.

Most single-byte locales share one SIM. The SIM features are as follows:

- Supports 101-key and 102-key keyboard mapping.
- Supports Alt-Numpad composing.

When you press the Alt key, the input method composes a character by using the next three numeric keys pressed. The three numeric keys represent the decimal encoding of the character. For example, entering the sequence XK_0, XK_9, XK_7 maps to the character *a* (097).

- Supports the Num-Lock state for the numeric keypad.
- Supports diacritical composing.
The e-umlaut key is an example of diacritical composing. To compose e-umlaut, the user presses the appropriate diacritical key (umlaut) followed by an alphabetic key (e). The specific set of diacritical keys in use depend on the locale and keyboard definition. When a space follows a diacritical key, the diacritical character represented by the key is returned if it is in the locale's code set.
- Does not require callback functions.
- Located in the `/usr/lib/nls/loc/sbcs.im` file. Most of the other localized input methods are aliases to this file.

Keymaps

This section discusses keymaps supported by single-byte input method (SIM).

The following keymaps are used by the SIM:

- `cs_CZ.ISO8859-2.imkeymap`
- `da_DK.ISO8859-1.imkeymap`
- `de_CH.ISO8859-1.imkeymap`
- `de_DE.ISO8859-1.imkeymap`
- `en_GB.ISO8859-1.imkeymap`
- `en_GB.ISO8859-1@alt.imkeymap`
- `en_US.ISO8859-1.imkeymap`
- `es_ES.ISO8859-1.imkeymap`
- `Et_EE.IBM-922 - imkeymap`
- `pl_PL.ISO8859-2@alt.imkeymap`
- `sq_AL.ISO8859-1.imkeymap`
- `fi_FI.ISO8859-1.imkeymap`
- `fi_FI.ISO8859-1@alt.imkeymap`
- `fr_BE.ISO8859-1.imkeymap`
- `fr_CA.ISO8859-1.imkeymap`
- `fr_CH.ISO8859-1.imkeymap`
- `fr_FR.ISO8859-1.imkeymap`
- `fr_FR.ISO8859-1@alt.imkeymap`
- `hr_HR.ISO8859-2.imkeymap`
- `hu_HU.ISO8859-2.imkeymap`
- `is_IS.ISO8859-1.imkeymap`
- `it_IT.ISO8859-1.imkeymap`
- `it_IT.ISO8859-1@alt.imkeymap`
- `nl_BE.ISO8859-1.imkeymap`
- `nl_NL.ISO8859-1.imkeymap`
- `no_NO.ISO8859-1.imkeymap`
- `pl_PL.ISO8859-2.imkeymap`
- `pt_BR.ISO8859-1.imkeymap`
- `pt_PT.ISO8859-1.imkeymap`
- `ro_RO.ISO8859-2.imkeymap`
- `sh_SP.ISO8859-2.imkeymap`
- `sl_SI.ISO8859-2.imkeymap`
- `sk_SK.ISO8859-2.imkeymap`

- sv_SE.ISO8859-1.imkeymap
- sv_SE.ISO8859-1@alt.imkeymap
- tr_TR.ISO8859-1.imkeymap

Reserved keysyms

The following keysyms are unique to this input method and are described in the `/usr/include/X11/aix_keysym.h` file.

Keysym	Hex value
XK_dead_acute	0x180000b4
XK_dead_grave	0x18000060
XK_dead_circumflex	0x1800005e
XK_dead_diaeresis	0x180000a8
XK_dead_tilde	0x1800007e
XK_dead_caron	0x180001b7
XK_dead_breve	0x180001a2
XK_dead_doubleacute	0x180001bd
XK_dead_degree	0x180000b0
XK_dead_abovedot	0x180001ff
XK_dead_macron	0x180000af
XK_dead_cedilla	0x180000b8
XK_dead_ogonek	0x180001b2
XK_dead_accentdieresis	0x180007ae

Modifiers

This section discusses the modifiers supported by the single-byte input method (SIM).

The following modifiers are used by the SIM:

Modifier	Hex value
ShiftMask	0x01
LockMask	0x02
ControlMask	0x04
Mod1Mask (Left-Alt)	0x08
Mod2Mask (Right-Alt)	0x10
Mod5Mask (Num Lock)	0x80

Traditional Chinese input method (TIM)

This section discusses the Traditional Chinese input methods (TIM).

The Traditional Chinese code sets consist of the following character groups:

- ASCII (English)
- Traditional Chinese characters

The Traditional Chinese character set contains more than 100,000 characters, but only about 5000 are frequently used. Each character comprises one to five components known as *radicals*.

The pronunciation of Traditional Chinese is represented by phonetic symbols called Dsu-Yin or Bo-Po-Mo-Fo. There are 37 phonetic symbols, as well as four intonation indicators. Chinese characters are represented by one to three phonetic symbols. The character can include one intonation symbol. The omission of an intonation symbol implies a fifth intonation accent.

TIM features

This section discusses the Traditional Chinese input method (TIM) features.

TIM features the following characteristics:

- The following input methods are used:

Tsang-Jye

Supports radicals to generate a character. Most frequently used by data entry personnel.

Simplified Tsang-Jye

Supports wildcard input and radicals. Also allows entry of partial characters.

Phonetic symbols

Inputs a character based on its pronunciation.

Internal Code

Generates characters by EUC hexadecimal, code point input.

Decimal value

Generates characters by decimal value. Can be invoked from any of the input modes.

- Half-width and full-width character input. Supports ASCII characters in both single-byte and multibyte modes.
- System-defined and user-definable character input.
- Auxiliary window to support all the candidate lists. Simplified Tsang-Jye and phonetic input methods generate a list of character candidates that contains the same input radicals or sound symbols. Users select characters by pressing the corresponding number.
- Over-the-spot pre-editing drawing area. Allows entry of radicals in reverse video area that temporarily covers the text line. The complete character is sent to the editor by pressing the conversion key.

The TIM file is found in the `/usr/lib/nls/loc/TW.im` directory.

The TIM keymap is found in the `/usr/lib/nls/loc/zh_TW.IBM-eucTW.imkeymap` directory.

Traditional Chinese character processing

TIM is invoked by pressing one of the input-method keys. Each radical or phonetic symbol is assigned to a key. The user inputs radicals or phonetic symbols to an over-the-spot pre-editing area. For Tsang-Jye and Internal Code input, a character is generated when the conversion key is pressed. Simplified Tsang-Jye and Phonetic input generate a list of candidates that display in a window. The user chooses the desired character by selecting the candidate number. Invalid input generates a beep and an error message.

The following special keys for the Traditional Chinese Input Method are defined on the Traditional Chinese 106-key keyboard.

Table 14. Special Traditional Chinese Keys

Key function	Keysym	Description of function
Tsang-Jye Shift key	XK_Chinese _Tsangjei	Invokes both the Tsang-Jye and Simplified Tsang-Jye input methods.
Phonetic Shift key	XK_Chinese _Phonetic	Invokes the Phonetic input method.
Half/Full-Width toggle key	XK_Chinese _Full_Half	Toggles between half-width and full-width.
Conversion key	XK_Convert	Converts radical and phonetic symbols or EUC code symbols into characters. Displays the candidate list in an auxiliary window, if needed.
Non-Conversion key	XK_Non _Convert	Interprets a phonetic symbol as a character.
English/Numeric key	XK_Alph_Num	Invokes ASCII mode.
ALT-Tsang-Jye Shift key	XK_Internal _Code	Invokes Internal Code input method.
ALT plus number keypad		Invoke the decimal value input method.

Universal input method

The universal input method is used in the Unicode/UTF-8 locales to provide complete multilingual input method support.

Features of the universal input method are as follows:

- Supports input method switching
 - Pressing the `Ctrl` key and the left `Alt` and the letter `i` simultaneously, presents a menu listing the other available input methods. Selecting an input method from the list remaps the keyboard and loads the given input method, allowing character entry using the loaded input method.
- Supports point and click character input
 - Pressing the `Ctrl` key and the left `Alt` and the letter `l` simultaneously, presents a menu listing the various categories of characters contained in the Unicode standard. Selecting a character list presents a matrix of the available characters from the list. Clicking on a given character will then send that character through the input method to the application.
 - Pressing the `Ctrl` key and the left `Alt` and the letter `c` returns to the application, or if already in the application, returns to the most recently used character list for point and click character entry.
- Supports the UTF-8 code set.

Keymap

This is the only Universal input Method keymap.

- `XX_XX.UTF-8.imkeymap`

Reserved keysyms

This section discusses the keysyms that are reserved by the input methods.

The keysyms listed are reserved for use by the input methods:

Keysyms	Hexadecimal representation
XK_dead_acute	0x180000b4
XK_dead_grave	0x18000060
XK_dead_circumflex	0x1800005e
XK_dead_diaeresis	0x180000a8
XK_dead_tilde	0x1800007e
XK_dead_caron	0x180001b7
XK_dead_breve	0x180001a2
XK_dead_doubleacute	0x180001bd
XK_dead_degree	0x180000b0
XK_dead_abovedot	0x180001ff
XK_dead_macron	0x180000af
XK_dead_cedilla	0x180000b8
XK_dead_ogonek	0x180001b2
XK_dead_accentdieresis	0x180007ae
XK_BunsetsuYomi	0x1800ff05
XK_MaeKouho	0x1800ff04
XK_ZenKouho	0x1800ff01
XK_KanjiBangou	0x1800ff02
XK_HenkanMenu	0x1800ff03
XK_LeftDouble	0x1800ff06
XK_RightDouble	0x1800ff07
XK_LeftPhrase	0x1800ff08
XK_RightPhrase	0x1800ff09
XK_ErInput	0x1800ff0a
XK_Reset	0x1800ff0b

Related concepts:

“Input methods” on page 119

For an application to run in the international environment for which globalization provides a base, input methods are needed. The Input Method is an application programming interface (API) that allows you to develop applications independent of a particular language, keyboard, or code set.

Reserved keysyms for Traditional Chinese

This section lists the Keysyms reserved for traditional Chinese.

Keysyms	Hexadecimal representation
XK_Full_Size	0xff42
XK_Phonetic	0xff48
XK_Alph_Num	0xaff50
XK_Non_Convert	0xaff52
XK_Convert	0xaff51
XK_Tsang_Jye	0xff47
XK_Internal_Code	0xff4a

Reserved keysyms for Simplified Chinese (ZIM and ZIM-UCS)

This section lists the keysyms reserved for Simplified Chinese (ZIM and ZIM-UCS).

Keysym	Hexadecimal representation
XK_Alph_Num	0xaff47
XK_Non_Convert	0xaff59
XK_Row_Column	0xaff48
XK_PinYin	0xaff49
XK_English_Chinese	0xaff50
XK_ABC	0xaff51
XK_Fivestroke	0xaff62
XK_User-defined	0xaff56
XK_Legend	0xaff55
XK_ABC_Set_Option	0xaff60
XK_Half_full	0xaff53

Message facility

It is necessary to keep messages separate from the program by providing them in the form of message catalogs that the program can access at run time. This arrangement facilitates translations of messages into various languages and make them available to a program based on a user's locale. To aid in this task, commands and subroutines are provided by the Message Facility.

Message source files containing application messages are created by the programmer and converted to message catalogs. The application uses these catalogs to retrieve and display messages, as needed. Translating message source files into other languages and then converting the files to message catalogs does not require changing and recompiling a program.

Related concepts:

“Separation of messages from programs” on page 1

It is necessary to keep messages separate from the programs and provide them in the form of message catalogs that a program can access at run time. It facilitates translations of messages into various languages and to make the translated messages available to the program based on a user's locale.

“AIXwindows checklist” on page 178

The remaining checklist items are specific to the AIXwindows systems.

“Program operation checklist” on page 174

Creating a message source file

The Message Facility provides commands and subroutines to retrieve and display program messages located in externalized message catalogs. A programmer creates a message source file containing application messages and converts it to a message catalog with the **genocat** command.

To create a message-text source file, open a file using any text editor. Enter a message identification number or symbolic identifier. Then enter the message text as shown in the following example:

```
1 message-text $      (This message is numbered)
2 message-text $      (This message is numbered)
OUTMSG message-text $ (This message has a symbolic identifier \
                      called OUTMSG)
4 message-text $      (This message is numbered)
```

Usage considerations

This section discusses the usage considerations.

Consider the following:

- One blank character must exist between the message ID number (or identifier) and the message text.
- A symbolic identifier must begin with an alphabetic character and can contain only letters of the alphabet, decimal digits, and underscores.
- The first character of a symbolic identifier cannot be a digit.
- The maximum length of a symbolic identifier is 64 bytes.
- Message ID numbers must be assigned in ascending order within a single message set, but need not be contiguous. 0 (zero) is not a valid message ID number.
- Message ID numbers must be assigned as if intervening symbolic identifiers are also numbered. If, for example, you had numbered the lines as in the previous example, 1, 2, OUTMSG, and 3, the program would contain an error, because the **mkcatdefs** command also assigns numbers to symbolic identifiers, and would have assigned number 3 to the OUTMSG symbolic identifier.

Note: Symbolic identifiers are specific to the message facility. Portability of message source files can be affected by the use of symbolic identifiers.

Adding comments to the message source file

You can include a comment anywhere in a message source file except within message text. Leave at least one space or tab (blank) after the \$ (dollar sign).

The following is an example of a comment:

```
$ This is a comment.
```

Comments do not appear in the message catalog generated from the message source file.

Comments can help developers in the process of maintaining message source files, translators in the process of translation, and writers in the process of editing and documenting messages. Use comments to

identify what variables, such as %s, %c, and %d, represent. For example, create a note that states whether the variable refers to a user, file, directory, or flag. Comments also should be used to identify obsolete messages.

For clarity, you should place a comment line directly beneath the message to which it refers, rather than at the bottom of the message catalog. Global comments for an entire set can be placed directly below the \$set directive.

Continuing messages on the next line

All text following the blank after the message number is included as message text, up to the end of the line. Use the escape character \ (backslash) to continue message text on the following line.

The \ (backslash) must be the last character on the line as in the following example:

```
5 This is the text associated with \
message number 5.
```

These two physical lines define the single-line message:

```
This is the text associated with message number 5.
```

Note: The use of more than one blank character after the message number or symbolic identifier is specific to the Message Facility. Portability of message source files can be affected by the use of more than one blank.

Including special characters in the message text

The \ (backslash) can be used to insert special characters into the message text.

These special characters are as follows:

Special character	Description
\n	Inserts a new-line character.
\t	Inserts a horizontal tab character.
\v	Inserts a vertical tab character.
\b	Inserts a backspace character.
\r	Inserts a carriage-return character.
\f	Inserts a form-feed character.
\\	Inserts a \ (backslash) character.
\ddd	Inserts a single-byte character associated with the octal value represented by the valid octal digits <i>ddd</i> . Note: One, two, or three octal digits can be specified. However, you must include a leading zero if the characters following the octal digits are also valid octal digits. For example, the octal value for \$ (dollar sign) is 44. To display \$5.00, use \0445.00, and not \445.00, or the 5 will be parsed as part of the octal value.
\xdd	Inserts a single-byte character associated with the hexadecimal value represented by the two valid hexadecimal digits <i>dd</i> . You must include a leading zero to avoid parsing errors (see the note about \ddd).
\xddd	Inserts a double-byte character associated with the hexadecimal value represented by the four valid hexadecimal digits <i>ddd</i> . You must include a leading zero to avoid parsing errors (see the note about \ddd).

Defining a character to delimit message text

You can use the \$quote directive in a message source file to define a character for delimiting message text. This character should be an ASCII character.

The format is:

```
$quote [character] [comment]
```

Use the specified character before and after the message text. In the following example, the **\$quote** directive sets the quote character to `_` (underscore), and then disables it before the last message, which contains quotation marks:

```
$quote _ Use an underscore to delimit message text
$set MSFAC Message Facility - symbolic identifiers
SYM_FORM _Symbolic identifiers can contain alphanumeric \
characters or the \_ (underscore character)\n_
SYM_LEN _Symbolic identifiers can be up to 65 \
characters long \n_
5 _You can mix symbolic identifiers and numbers \n_
$quote
MSG_H Remember to include the _msg_h_ file in your program\n
```

The last **\$quote** directive in the previous example disables the underscore character.

In the following example, the **\$quote** directive defines `"` (double quotation marks) as the quote character. The quote character must be the first non-blank character following the message number. Any text following the next occurrence of the quote character is ignored.

```
$quote " Use a double quote to delimit message text
$set 10 Message Facility - Quote command messages
1 "Use the $quote directive to define a character \
\n for delimiting message text"
2 "You can include the \"quote\" character in a message \n \
by placing a \\ in front of it"
3 You can include the "quote" character in a message \n \
by having another character as the first nonblank \
\n character after the message ID number
$quote
4 You can disable the quote mechanism by \n \
using the $quote directive without a character \n\
after it
```

The preceding example illustrates two ways the quote character can be included in message text:

- Place a `\` (backslash) in front of the quote character.
- Use some other character as the first non-blank character following the message number. This disables the quote character only for that message.

The preceding example also shows the following:

- A `\` (backslash) is still required to split a quoted message across lines.
- To display a `\` (backslash) in a message, place another `\` (backslash) in front of it.
- You can format a message with a new-line character by using `\n`.
- Using the **\$quote** directive with no character argument disables the quote mechanism.

Assigning message set numbers and message ID numbers

All message sets require a set number or symbolic identifier.

Use the **\$set** directive in a source file to give a group of messages a number or identifier:

```
$set n [ comment ]
```

The message set number is specified by the value of *n*, a number between 1 and `NL_SETMAX`. Instead of a number, you can use a symbolic identifier. All messages following the **\$set** directive are assigned to that set number until the next occurrence of a **\$set** directive. The default set number is 1. Set numbers must be assigned in ascending order, but need not be in series. Empty sets are created for skipped numbers. However, large gaps in the number sequence can decrease efficiency and performance. Moreover, performance is not enhanced by using more than one set number in a catalog.

You can also include a comment in the **\$set** directive, as follows:

```
$set 10 Communication Error Messages
```

```
$set OUTMSGSGS Output Error Messages
```

Many AIX message sets have a symbolic identifier of the form **MS_PROG**, where **MS** represents Message Set and **PROG** is the name of the program or utility related to the message set. For example:

```
$set MS_WC Message Set for the wc Utility
```

```
$set MS_XLC1 Message Set 1 for the C For AIX compiler
```

```
$set MS_XLC2 Message Set 2 for the C For AIX compiler
```

Removing messages from a catalog

This section discusses how to remove messages from a catalog using the **\$delset** directive.

The **\$delset** directive removes all of the messages belonging to a specified set from an existing catalog:

```
$delset n [ comment ]
```

The message set is specified by *n*. The **\$delset** directive must be placed in the proper set-number order with respect to any **\$set** directives in the same source file. You can also include a comment in the **\$delset** directive.

Length of message text

The section describes the maximum display length of message text.

The **\$len** directive establishes the maximum display length of message text:

```
$len [n [ comment ] ]
```

If *n* is not specified or if the **\$len** directive is not included, the message text display is set to the **NL_TEXTMAX** value. The message-text display length is the maximum number of bytes allowed for a message. Any subsequent specification of a **\$len** directive overrides a previous specification. The value of *n* cannot exceed the **NL_TEXTMAX** value.

Content of message text

Whenever possible, tell users exactly what has happened and what they can do to remedy the situation.

The following example shows how cause and recovery information can improve a message:

```
Original Message: Bad arg
```

```
Revised Message: Specify year as a value between 1 and 9999.
```

The message `Bad arg` does not help users much; whereas the message `Do not specify more than 2 files on the command line` tells users exactly what they must do to make the command work. Similarly, the message `Line too long` does not give recovery information to users. The message `Line cannot exceed 20 characters` provides the missing information.

Examples of message source files

This topic will show you examples of message source files.

The following example message source file uses numbers for message ID numbers and for message set numbers:

```
$ This is a message source file sample.  
$ Define the Quote Character.  
$quote "  
$set 1 This is the set 1 of messages.  
1 "The specified file does not have read permission on\n"  
2 "The %1$s file and the %2$s file are same\n"
```

```

3 "Hello world!\n"
$Define the quote character
$quote '
$set 2 This is the set 2 of messages
1      'fieldef: Cannot open %1$s \n'
2      'Hello world\n'

```

The following example message source file uses symbolic identifiers for message ID numbers and for message set numbers:

```

$ This is a message source file sample.
$ Define the Quote Character.
$quote "
$set MS_SET1 This is the set 1 of messages.
MSG_1  "The specified file does not have read permission on\n"
MSG_2  "The %1$s file and the %2$s file are same\n"
MSG_3  "Hello world\n"
$Define the quote character
$quote
$set 2 This is the set 2 of messages.
$EMSG_1 'fieldef: Cannot open %1$s\n'
$EMSG_2 'Hello world!\n'

```

The following examples show how symbolic identifiers can make the specification of a message more understandable:

```

catgets(cd, 1, 1, "default message")
catgets(cd, MS_SET1, MSG_1, "default message")

```

Creating a message catalog

The Message Facility provides commands and subroutines to retrieve and display program messages located in externalized message catalogs. A programmer creates a message source file containing application messages and converts it to a message catalog. Translating message source files into other languages and then converting the files to message catalogs does not require changing or recompiling a program.

To create a message catalog, process your completed message source file with the message facility's **gencat** command. This command can be used in the following ways:

- Use the **gencat** command to process a message source file containing set numbers, message ID numbers, and message text. Message source files containing symbolic identifiers cannot be processed directly by the **gencat** command. The following example uses the information in the **x.msg** message source file to generate a catalog file:

```
gencat x.cat x.msg
```

- Use the **mkcatdefs** command to preprocess a message source file containing symbolic identifiers. The resulting file is then piped to the **gencat** command. The **mkcatdefs** command produces a *SymbolName_msg.h* file containing definition statements. These statements equate symbolic identifiers with set numbers and message ID numbers assigned by the **mkcatdefs** command. The *SymbolName_msg.h* file should be included in programs using these symbolic identifiers. The **mkcatdefs** command is specific to AIX. The following example uses the information in the **x.msg** message source file to generate the **x_msg.h** header file:

```
mkcatdefs x x.msg
```

- Use the **runcat** command to automatically process a source file containing symbolic identifiers. The **runcat** command invokes the **mkcatdefs** command and pipes its output to the **gencat** command. The **runcat** command is specific to AIX. The following example uses the information in the **x.msg** message source file to generate the **x_msg.h** header file and the **X.cat** catalog file:

```
runcat x x.msg
```

The preceding example is equivalent to the following example:

```
mkcatdefs x x.msg | gencat x.cat
```

If a message catalog with the name specified by the *CatalogFile* parameter exists, the **gencat** command modifies the catalog according to the statements in the message source files. If a message catalog does not exist, the **gencat** command creates a catalog file with the name specified by the *CatalogFile* parameter.

You can specify any number of message text source files. Multiple files are processed in the sequence you specify. Each successive source file modifies the catalog. If you do not specify a source file, the **gencat** command accepts message source data from standard input.

Noun or noun phrase (ex: Client certificates)

This topic discusses catalog sizing and the macros used to define the sizes.

A message catalog can be virtually any size. The maximum numbers of sets in a catalog, messages in a catalog, and bytes in a message are defined in the `/usr/include/limits.h` file by the following macros:

Macro	Description
NL_SETMAX	Specifies the maximum number of set numbers that can be specified by the <code>\$set</code> directive. If the <code>NL_SETMAX</code> limit is exceeded, the gencat command issues an error message and does not create or update the message catalog.
NL_MSGMAX	Specifies the maximum number of message ID numbers allowed by the system. If the <code>NL_MSGMAX</code> limit is exceeded, the gencat command issues an error message and does not create or update the message catalog.
NL_TEXTMAX	Specifies the maximum number of bytes a message can contain. If the <code>NL_TEXTMAX</code> limit is exceeded, the gencat command issues an error message and does not create or update the message catalog.

Examples

This section discusses the options on how to create a message catalog from a source file.

Often begins with a definition, answering the question, "What is this?"

- This example shows how to create a message catalog from a source file containing message identification numbers. The following is the text of the **hello.msg** message source file:

```
$ file: hello.msg
$set 1  prompts
1 Please, enter your name.
2 Hello, %s \n
$ end of file: hello.msg
```

To create the **hello.cat** message catalog from the **hello.msg** source file, type:

```
gencat hello.cat hello.msg
```

- This example shows how to create a message catalog from a source file with symbolic references. The following is the text of the **hello.msg** message source file that contains symbolic references to the message set and the messages:

```
$ file: hello.msg
$quote "
$set PROMPTS
PLEASE "Please, enter your name."
HELLO "Hello, %s \n"
$ end of file: hello.msg
```

To process the **hello.msg** and **msgerrs** message source files, type:

```
runcat hello hello.msg
runcat msgerrs msgerrs.msg /usr/lib/nls/msg/$LANG/msgerrs.cat
```

The **runcat** command invokes the **mkcatdefs** and **gencat** commands. The first call to the **runcat** command takes the **hello.msg** source file and uses the second parameter, `hello`, to produce the **hello.cat** message catalog and the **hello_msg.h** definition file.

The **hello_msg.h** definition file contains symbolic names for the message catalog and symbolic IDs for the messages and sets. The symbolic name for the **hello.cat** message catalog is MF_HELLO. This name is produced automatically by the **mkcatdefs** command.

The second call to the **runcat** command takes the **msgerrs.msg** source file and uses the first parameter, **msgerrs**, to produce the **msgerrs_msg.h** definition file.

Because the third parameter, **/usr/lib/nls/msg/\$LANG/msgerrs.cat**, is present, the **runcat** command uses this parameter for the catalog file name. This parameter is an absolute path name that specifies exactly where the **runcat** command must put the file. The symbolic name for the **msgerrs.cat** catalog is MF_MSGERRS.

Displaying messages outside of an application program

The following commands allow you to display messages outside of an application program. These commands are specific to AIX.

Command	Description
dspcat	Displays the messages contained in the specified message catalog. The following example displays the messages located in the x.cat message source file: <pre>dspcat x.cat</pre>
dspmsg	Displays a single message from a message catalog. The following example displays the message located in the x.cat message source file that has the ID number of 1 and the set number of 2: <pre>dspmsg x.cat -s 2 1</pre> You can use the dspmsg command in shell scripts when a message must be obtained from a message catalog.

Displaying messages with an application program

This topic will discuss the items that must be included in your application programming.

When programming with the Message Facility, you must include the following items in your application program:

- The *CatalogFile_msg.h* definition file created by the **mkcatdefs** or **runcat** command if you used symbolic identifiers in the message source file, or the **limits.h** and **nl_types.h** files if you did not use symbolic identifiers
- A call to initialize the locale environment
- A call to open a catalog
- A call to read a message
- A call to display a message
- A call to close the catalog

The following subroutines provide the services necessary for displaying program messages with the message facility:

Subroutine	Description
setlocale	Sets the locale. Specify the LC_ALL environment variable in the call to the setlocale subroutine for the preferred message catalog language.
catopen	Opens a specified message catalog and returns a catalog descriptor, which you use to retrieve messages from the catalog.
catgets	Retrieves a message from a catalog after a successful call to the catopen subroutine.
printf	Converts, formats, and writes to the stdout (standard output) stream.
catclose	Closes a specified message catalog.

The following C program, `hello`, illustrates opening the `hello.cat` catalog with the `catopen` subroutine, retrieving messages from the catalog with the `catgets` subroutine, displaying the messages with the `printf` subroutine, and closing the catalog with the `catclose` subroutine.

```
/* program: hello */
#include <nl_types.h>
#include <locale.h>
nl_catd catd;
main()
{
    /* initialize the locale */
    setlocale (LC_ALL, "");
    /* open the catalog */
    catd=catopen("hello.cat",NL_CAT_LOCALE);
    printf(catgets(catd,1,1,"Hello World!"));
    catclose(catd);          /* close the catalog */
    exit(0);
}
```

In the previous example, the `catopen` subroutine refers to the `hello.cat` message catalog only by file name. Therefore, you must make sure that the `NLSPATH` environment variable is set correctly. If the message catalog is successfully opened by the `catopen` subroutine, the `catgets` subroutine returns a pointer to the specified message in the `hello.cat` catalog. If the message catalog is not found or the message does not exist in the catalog, the `catgets` subroutine returns the `Hello World!` default string.

Understanding the `NLSPATH` environment variable

The `NLSPATH` environment variable specifies the directories to search for message catalogs.

The `catopen` subroutine searches these directories in the order specified when called to locate and open a message catalog. If the message catalog is not found, the message-retrieving routine returns the program-supplied default message. See the `/etc/environment` file for the `NLSPATH` default path.

Retrieving program-supplied default messages

All message-retrieving routines return the program-supplied default message text if the desired message cannot be retrieved for any reason. Program-supplied default messages are generally brief one-line messages that contain no message numbers in the text. Users who prefer these default messages can set the `LC_MESSAGES` category to the C locale or unset the `NLSPATH` environment variable. When none of the `LC_ALL`, `LC_MESSAGES`, or `LANG` environment variables are set, the `LC_MESSAGES` category defaults to the C locale.

Setting the language hierarchy

Multilingual users may specify a language hierarchy for message text.

To set the language hierarchy for the system default or for an individual user, see “Changing the language environment” on page 5, or use `SMIT`. To use `SMIT`, to set the language hierarchy, type the `SMIT` fastpath `smit mlang` at the command line.

Select **Change / Show Language Hierarchy**.

OR

At the command line, type:

```
smit
```

Select **System Environments**.

Select **Manage Language Environment**.

Select **Change / Show Language Hierarchy**.

Example of retrieving a message from a catalog

This example has three parts: the message source file, the command used to generate the message catalog file, and an example program using the message catalog.

1. The following example shows the **example.msg** message source file:

```
$quote "  
$ every message catalog should have a beginning set number.  
$set MS_SET1  
MSG1 "Hello world\n"  
MSG2 "Good Morning\n"  
ERRMSG1 "example: 1000.220 Read permission is denied for the file  
%s.\n"  
$set MS_SET2  
MSG3 "Howdy\n"
```

2. The following command uses the **example.msg** message source file to generate the **example.h** header file and the **example.cat** catalog file in the current directory:

```
runcat example example.msg
```

3. The following example program uses the **example.h** header file and accesses the **example.cat** catalog file:

```
#include <locale.h>  
#include <nl_types.h>  
#include "example_msg.h" /*contains definitions for symbolic  
                           identifiers*/  
  
main()  
{  
    nl_catd catd;  
    int error;  
  
    (void)setlocale(LC_ALL, "");  
  
    catd = catopen(MF_EXAMPLE, NL_CAT_LOCALE);  
    /*  
    ** Get the message number 1 from the first set.  
    */  
    printf( catgets(catd,MS_SET1,MSG1,"Hello world\n") );  
  
    /*  
    ** Get the message number 1 from the second set.  
    */  
    printf( catgets(catd, MS_SET2, MSG3,"Howdy\n") );  
    /*  
    ** Display an error message.  
    */  
    printf( catgets(catd, MS_SET1, ERRMSG1,"example: 100.220  
        Permission is denied to read the file %s.\n") ,  
        filename);  
    catclose(catd);  
}
```

Write messages

This section will give you helpful tips to make your message meaningful and concise.

The following tips help you make messages meaningful and concise:

- Plan for the globalization of all messages, including messages that are displayed on panels.
- Allow sufficient space for translated messages to be displayed. Translated messages often occupy more display columns than the original message text. In general, allow about 20% to 30% more space for translated messages, but in some cases, you might need to allow 100% more space for translated messages.

- Use message catalogs to externalize any user and error messages. X applications can use resource files to externalize messages for each locale.
- Provide default messages.
- Make each message in a message source file be a complete entity. Building a message by concatenating parts makes translation difficult.
- Use the **\$len** directive in the message source file to control the maximum display length of the message text. (The **\$len** directive is specific to the Message Facility.)
- Use symbolic identifiers to specify the set number and message number. Programs should refer to set numbers and message numbers by their symbolic identifiers, not by their actual numbers. (The use of symbolic identifiers is specific to the Message Facility.)
- Facilitate the reordering of sentence clauses by numbering the %s variables. This allows the translator to reorder the clauses if needed. For example, if a program needs to display the English message: The file %s is referenced in %s, a program may supply the two strings as follows:

```
printf(message_pointer, name1, name2)
```

The English message numbers the %s variables as follows:

The file %1\$s is referenced in %2\$s\n

The translated equivalent of this message may be:

%2\$s contains a reference to file %1\$s\n

- Do not use **sys_errlist[errno]** to obtain an error message. This defeats the purpose of externalizing messages. The **sys_errlist[]** is an array of error messages provided only in the English language. Use **strerror(errno)**, as it obtains messages from catalogs.
- Do not use **sys_siglist[signo]** to obtain an error message. This defeats the purpose of externalizing messages. The **sys_siglist[]** is an array of error messages provided only in the English language. Use **psignal()**, as it obtains messages from catalogs.
- Use the message comments facility to aid in the maintenance and translation of messages.
- In general, create separate message source files and catalogs for messages that apply to each command or utility.

Describing command syntax in messages

This section will show command syntax in usage statements.

- Show the command syntax in the usage statement. For example, a possible usage statement for the **rm** command is:

```
Usage: rm [-firRe] [--] File ...
```
- Capitalize the first letter of such words as File, Directory, String, and Number in usage statement messages.
- Do not abbreviate parameters on the command line. For example, Num spelled out as Number can be more easily translated.
- Use only the following delimiters in usage statement messages:

Delimiter	Description
[]	Encloses an optional parameter.
{ }	Encloses multiple parameters, one of which is required.
	Separates parameters that cannot both be chosen. For example, [a b] indicates that you can choose a, b, or neither a nor b; and {a b} indicates that you must choose a or b.
...	Follows a parameter that can be repeated on the command line. Note that there is a space before the ellipsis.
-	Indicates standard input.

- Do not use any delimiters for a required parameter that is the only choice. For example:

```
banner String
```
- Put a space character between flags that must be separated on the command line. For example:

```
unget [-n] [-rSID] [-s] {File|-}
```

- Do not separate flags that can be used together on the command line. For example:

```
wc [-cwl] {File ...|-}
```

- Put flags in alphabetic order when the order of the flags on the command line does not make a difference. Put lowercase flags before uppercase flags. For example:

```
get -aAijlmM
```

- Use your best judgment to determine where you should end lines in the usage statement message. The following example shows a lengthy usage statement message:

```
Usage: get [-e|-k] [-c Cutoff] [-i List] [-r SID] [-w String]
        [-x List] [-b] [-gmpst] ...
```

Continue the usage information on a second line, if necessary. For example:

```
Usage: get [-e|-k] [-c Cutoff] [-i List] [-r SID] [-w String]
        [-x List] [-b] [-gmpst] [-l[p]] File ...
```

Writing style for messages

Clear writing aids in message translation. The following guidelines on the writing style of messages include terminology, punctuation, mood, voice, tense, capitalization, format, and other usage questions.

- Write concise messages. One-sentence messages are preferable.
- Use complete-sentence format.
- Add articles (a, an, the) when necessary to eliminate ambiguity.
- Capitalize the first word of the sentence, and use a period at the end of the sentence.
- Use the present tense. Do not use future tense in a message. For example, use the sentence:
The `cal` command displays a calendar.

Instead of:

The `cal` command will display a calendar.

- Do not use the first person (I or we) in messages.
- Avoid using the second person (you) except in help and interactive text.
- Use active voice. The following example shows how a message written in passive voice can be turned into an active voice message.
Passive: Month and year must be entered as numbers.
Active: Enter month and year as numbers.
- Use the imperative mood (command phrase) and active verbs such as specify, use, check, choose, and wait.
- State messages in a positive tone. The following example shows a negative message made more positive.
Negative: Don't use the `f` option more than once.
Positive: Use the `-f` flag only once.
- Use words only in the grammatical categories shown in a dictionary. If a word is shown only as a noun, do not use it as a verb. For example, do not *solution* a problem or *architect* a system.
- Do not use prefixes or suffixes. Translators might not know what words beginning with *re-*, *un-*, *in-*, or *non-* mean, and the translations of messages that use prefixes or suffixes might not have the meaning you intended. Exceptions to this rule occur when the prefix is an integral part of a commonly used word. For example, the words *previous* and *premature* are acceptable; the word *nonexistent* is not acceptable.
- Do not use parentheses to show singular or plural, as in *error(s)*, which cannot be translated. If you must show singular and plural, write *error* or *errors*. You might also be able to revise the code so that different messages are issued depending on whether the singular or plural of a word is required.
- Do not use contractions.

- Do not use quotation marks, both single and double quotation marks. For example, do not use quotation marks around variables such as %s, %c, and %d or around commands. Users might interpret the quotation marks literally.
- Do not hyphenate words at the ends of lines.
- Do not use the standard highlighting guidelines in messages, and do not substitute initial or all caps for other highlighting practices. (Standard highlighting includes such guidelines as boldface for commands, subroutines, and files; italics for variables and parameters; typewriter or courier font for examples and displayed text.)
- Do not use the and/or construction. This construction does not exist in other languages. Usually it is better to say or to indicate that it is not necessary to do both.
- Use the 24-hour clock. Do not use a.m. or p.m. to specify time. For example, write 1:00 p.m. as 1300.
- Avoid acronyms. Only use acronyms that are better known to your audience than their spelled-out version. To make a plural of an acronym, add a lowercase s without an apostrophe. Verify that the acronym is not a trademark before using it.
- Do not construct messages from clauses. Use flags or other means within the program to pass on information so that a complete message might be issued at the proper time.
- Do not use hard-coded text as a variable for a %s string in a message.
- End the last line of the message with \n (indicating a new line). This applies to one-line messages also.
- Begin the second and remaining lines of a message with \t (indicating a tab).
- End all other lines with \n\ (indicating a new line).
- Force a newline on word boundaries where needed so that acceptable message strings display. The **printf** subroutine, which often is used to display the message text, disregards word boundaries and wraps text whenever necessary, sometimes splitting a word in the middle.
- If, for some reason, the message should not end with a newline character, leave writers a comment to that effect.
- Precede each message with the name of the command that called the message, followed by a colon. The following example is a message containing a command name:
OPIE "my_example: Opening the file."
- Do not tell the user to Try again later, unless the system is overloaded. The need to try again should be obvious from the message.
- Use the word "parameter" to describe text on the command line, the word "value" to indicate numeric data, and the words "command string" to describe the command with its parameters.
- Do not use commas to set off the one-thousandth place in values. For example, use 1000 instead of 1,000.
- If a message must be set off with an * (asterisk), use two asterisks at the beginning of the message and two at asterisks at the end of the message. For example:
** Total **
- Use the words "log in" and "log off" as verbs. For example:
Use the words "log in" and "log off" as verbs. For example:
- Use the words "user name," "group name," and "login" as nouns. For example:
The user is sam.
The group name is staff.
The login directory is /u/sam.
- Do not use the word "superuser." Note that the root user might not have all privileges.
- Use the following frequently occurring standard messages where applicable:

Preferred Standard Message

Cannot find or open the file.
Cannot find or access the file.
The syntax of a parameter is not valid.

Less Desirable Message

Can't open filename.
Can't access
syntax error

Culture-specific data handling

Culture-specific data handling may be part of a program, and such a program may supply different data for different locales. In addition, a program may use different algorithms to process character data based on the language and culture.

For example, recognition of the start and end of a word and the method of hyphenation of a word across two lines varies depending on the locale. Programs that deal with such functionality need access to these tables or algorithms based on the current locale setting at run time. You can handle such programs in the following ways:

- Compile all the algorithms and tables, and load them with the program.
This method makes it difficult to add or modify the algorithms and tables. Whenever a new algorithm or table is added, the entire program must be relinked.
- Keep the locale-specific algorithms and tables in a file, and load them at run time, depending on the current locale setting.
This method makes it easier to modify and add algorithms and tables. However, there is no standard defined way to load algorithms. In AIX, you can achieve this using the **load** subroutine, but programs that use the **load** subroutine might not be portable to other systems.

Culture-specific tables

If the culture-specific data can be processed by accessing tables based on the current locale setting, then this can be accomplished by using the standard file I/O subroutines (**fopen**, **fread**, **open**, **read**, and so on). Such tables must be provided in the directory defined in **/usr/lpp/Name** where *Name* is the name of the particular application under the appropriate locale name.

Standard path prefix

/usr/lpp/Name (AIX-specific pathname)

Culture-specific directory

Obtain the current locale for the appropriate category that describes the tables. Concatenate it to the above prefix.

Access

Use standard file access subroutines (**fopen**, **fread**, and so on) as appropriate.

Culture-specific algorithms

The culture-specific algorithms reside in the **/usr/lpp/Name/%L** directory. Here %L represents the current locale setting for the appropriate category.

Use the **load** subroutine to access program-specific algorithms from an object module.

Standard path prefix

/usr/lpp/Name

Culture-specific directory

Obtain the current locale for the appropriate category. Concatenate it to the above prefix.

Method

Concatenate the method name to it.

Example of loading a culture-specific module for Arabic text for an application

This section discusses loading a culture-specific module for Arabic text for an application.

Header file

This section discusses the one structure in the `method.h` include file.

The `methods.h` include file has one structure as follows:

```
struct Methods {
    int    version;
    char   *(*hyphen)();
    char   *(*wordbegin)();
    char   *(*wordend)();
};
```

Main program

In this example, the program name is `textpr`.

The main program determines the module to load and invokes it. Note that the `textpr.h` include file is used to specify the path name of the load object. This way, the path name, which is system-specific, can be changed easily.

```
#include <stdio.h>;
#include <errno.h>;
#include "methods.h"
#include "textpr.h" /* contains the pathname where
                    the load object can be found */

extern int  errno;

main()
{
    char libpath[PATH_MAX]; /* stores the full pathname of the
                           load object */
    char *prefix_path=PREFIX_PATH; /* from textpr.h */
    char *method=METHOD; /* from textpr.h */
    int (*func)();
    char *path;
    /* Methods */
    int  ver;
    char *p;
    struct Methods *md;

    setlocale(LC_ALL, "");

    path = setlocale(LC_CTYPE, 0); /* obtain the locale
                                   for LC_CTYPE category */
    /* Construct the full pathname for the
    /* object to be loaded
    */
    strcpy(libpath, prefix_path);
    strcat(libpath, path);
    strcat(libpath, "/");
    strcat(libpath, method);

    func = load(conv, 1, libpath); /* load the object */
    if(func==NULL){
        strerror(errno);
        exit(1);
    }
    /* invoke the loaded module */
    md =(struct Methods *) func(); /* Obtain the methods
                                   structure */

    ver = md->version;
```

```

        /* Invoke the methods as needed */
        p = (md-&gt;hyphen)();
        p = (md-&gt;wordbegin)();
        p = (md-&gt;wordend)();
    }

```

Methods

This section contains culture-specific algorithms.

In this example, it provides the Arabic method. The `method.c` program follows:

```

#include "methods.h"

char *Arabic_hyphen(char *);
char *Arabic_wordbegin(char *);
char *Arabic_wordend(char *);

static struct Methods ArabicMethods= {
    1,
    Arabic_hyphen,
    Arabic_wordbegin,
    Arabic_wordend
};

struct Methods *start_methods()
{
    /* startup methods */
    return ( &ArabicMethods);
}

char *Arabic_hyphen(char *string)
{
    /* Arabic hyphen */
    return( string );
}

char *Arabic_wordbegin(char *string)
{
    /*Arabic word begin */);
    return( string );
}

char *Arabic_wordend(char *string)
{
    /* Arabic word end */;
    return( string);
}

```

Include file

The `textpr` include file contains the path name of the module to be loaded.

```

#define PREFIX_PATH "/usr/lpp/textpr"
        /* This is an AIX-specific pathname */

```

Layout (bidirectional text and character shaping) overview

Bidirectional (BIDI) text results when texts of different direction orientation appear together. For example, English text is read from left to right. Arabic and Hebrew texts are read from right to left. If both English and Hebrew texts appear on the same line, the text is bidirectional.

For further information about directional text and character shaping, including a list of available publications, see the following web address:

<http://www.opengroup.org>

Write bidirectional text according to the following guidelines:

- Arabic and Hebrew words are written from right to left. (A character string is considered a word for the purposes of sequencing in an alphanumeric environment.)
- Numbers and English quotations are written from left to right.
- Digits and their punctuation marks are written from left to right.

Bidirectional script is read from right to left and from top to bottom.

If the embedded text is contained in one line, the text is written from left to right and embedded in the bidirectional text. However, if the embedded text is split between two or more lines, the correct order must be maintained in the left-to-right portions to allow top-to-bottom reading.

For example, right-to-left text embedded in left-to-right text that is contained in one line is written as follows:

```
THERE IS txet lanoitceridib deddebme IN THIS SENTENCE.
```

Right-to-left text embedded in left-to-right text that is split between two lines is written as follows:

```
THERE IS senil owt neewteb tilps si taht txet lanoitceridib deddebme IN THIS SENTENCE.
```

Both texts maintain readability even though the embedded text is split.

“Bidirectionality and character shaping” on page 11

An globalized program may need to handle bidirectionality of text and character shaping.

Data streams

This section discusses data streams for the bidirectional text environment.

Bidirectional text environments use the following data streams:

Data stream	Description
Visual Data Streams	<p>The system organizes characters in the sequence in which they are presented on the screen.</p> <p>If a visual data stream is presented from left to right, the first character of the data stream is on the left side of the viewport (screen, window, line, field, and so on). If the same data stream is presented on a right-to-left viewport, the initial character of the data stream is on the right.</p> <p>If a language of opposite writing orientation is embedded in the visual data stream, the sequence of each text is preserved when the viewport orientation is reversed. For example, (the lowercase text represents bidirectional text) if the keystroke order is :</p> <pre>THERE IS bidirectional text IN THIS SENTENCE.</pre> <p>then the visual data stream is:</p> <pre>THERE IS txet lanoitceridib IN THIS SENTENCE.</pre> <p>This visual data stream's presentation on a left-to-right viewport is left-justified, as follows:</p> <pre>THERE IS txet lanoitceridib IN THIS SENTENCE. -----> <-----></pre> <p>The arrows indicate reading direction.</p> <p>If you change the viewport orientation to right-to-left, the visual data stream is reversed, right-justified, and unreadable, as follows:</p> <pre>.ECNETNES SIHT NI bidirectional text SI EREHT <-----> <-----></pre> <p>Thus, if English text is embedded in Arabic or Hebrew text, both texts are in proper reading order only on a left-to-right viewport. The same is true for Arabic or Hebrew embedded in English. Reversing the viewport orientation makes both texts unreadable.</p>
Logical Data Streams	<p>The system organizes characters in a readable sequence. The bidirectional presentation-management functions arrange text strings in a readable order.</p> <p>If a logical data stream is presented on a left-to-right viewport, the initial character of the data stream is presented on the left side. If the same data stream is presented on a right-to-left viewport, the initial character of the data stream is presented on the right side, though it is still presented in a readable order.</p> <p>If a language of opposite writing orientation is embedded in the logical data stream, the orientations of each text are preserved by the bidirectional presentation-management functions. For example, if the keystroke order is:</p> <pre>THERE IS bidirectional text IN THIS SENTENCE.</pre> <p>then the logical data stream is the same. For example:</p> <pre>THERE IS bidirectional text IN THIS SENTENCE.</pre> <p>This logical data stream's presentation on a left-to-right viewport (left-justified) is as follows:</p> <pre>THERE IS txet lanoitceridib IN THIS SENTENCE. -----> <-----></pre> <p>The logical data stream's presentation on a right-to-left viewport (right-justified) is as follows:</p> <pre>IN THIS SENTENCE. txet lanoitceridib THERE IS -----> <-----></pre> <p>The logical data stream is readable on both viewport orientations.</p>

Cursor movement

This section discusses cursor movement on a screen when it contains bidirectional text.

Cursor movement on a screen containing bidirectional text is as follows:

Cursor movement	Description
Visual	<p>The cursor moves from its current position left or right to the next character, or up or down to the next row. For example, if the cursor is located at the end of the first left-to-right part of a mixed sentence: THERE IS_txet lanoitceridib IN THIS SENTENCE.</p> <p>then, moving the cursor visually to the right causes it to move one character to the right, as follows: THERE IS txet lanoitceridib IN THIS SENTENCE.</p> <p>The cursor moves without regard to the contents of the text.</p>
Logical	<p>The cursor moves from its current position to the next or previous character in the data stream. The character may be adjacent to the cursor's position, elsewhere in the same line, or on another line on the screen. Logical cursor movement requires scanning the data stream to find the next logical character. For example, if the cursor is located at the end of the first left-to-right part of a mixed sentence: THERE IS_txet lanoitceridib IN THIS SENTENCE.</p> <p>then, moving the cursor logically to the next character causes the data stream to be scanned to find the next logical character. The cursor moves to the next logical part of the sentence, as follows: THERE IS txet lanoitceridib_IN THIS SENTENCE.</p> <p>The cursor moves according to content.</p>

Character shaping

Character shaping occurs when the shape of a character is dependent on its position in a line of text. In some languages, such as Arabic, characters have different shapes depending on their position in a string and on the surrounding characters.

The following characteristics determine character shaping in Arabic script:

- The written language has no equivalent to capital letters.
- The characters have different shapes, depending on their position in a string and on the surrounding characters.
- The written language is cursive. Most characters of a word are connected, as in English handwriting.
- Joined characters can form nonspacing characters. Additionally, a character can have a vowel or diacritic mark written over or under it.
- Characters can vary in length, resulting in an output of two coded shapes.

Methods of character shaping:

Implement character shaping separately from other system components. However, character shaping should be accessible as a utility by other system components.

The system may use character shaping in the following ways:

- As the user enters data into the computer, the system uses character shaping to shape the characters. The system stores these characters in their shaped format.

This method avoids the need to use character shaping every time these characters are displayed. This method is meant for static data such as menus and help. This method requires preprocessing for correct sorting, searching, or indexing of the characters.

The characters may need reshaping after processing for proper presentation.

- As the user enters data into the computer, the system stores the characters in their unshaped format.

This method allows for sorting, searching or indexing of the characters. However, the system must use character shaping every time the characters are displayed.

Base shapes are isolated shapes that were not generated by character shaping. Use base shapes during editing, searching for character strings, or other text operations. Use shaping only when the text is displayed or printed. If characters are stored in their shaped form, the system must deshape them before sorting, collating, searching, or indexing. Character shapes that are not shape-determined according to their position in a string are needed for specific character-handling applications, as well as for communication with different coding environments.

Contextual character shaping:

In general, contextual character shaping is the selection of the required shape of a character in a given font depending on its position in a word and its surrounding characters.

The following shapes are possible:

Character shaping	Description
Isolated	A character that is connected to neither a preceding nor succeeding character
Final	A character that is connected to a preceding character but not with a succeeding character
Initial	A character connected to a succeeding character but not with a preceding character
Middle	A character connected to both a preceding and succeeding character

A character may also have any of the following characteristics:

- Connecting to a preceding character
- Connecting to a succeeding character
- Allowing surrounding characters' connections to pass through it

Acronyms, part numbers, and graphic characters do not need contextual character shaping. To properly enter these characters, turn off the contextual character shaping and use a specific keyboard interface for exact selection of the desired shape. Tag these characters by field, line, or control character for later presentation.

Supported languages and locales

In addition to the many locales supported in full client mode, AIX now provides “Server Side Support” for many new Unicode locales.

Server-side locale support provides the following features:

- Storage and manipulation of Unicode strings
- Conversion facilities (iconv)
- Formatting and parsing functions for numbers, currencies, date, time, and messages
- Message facility to support translations of messages into various languages and availability to a program that is based on a user locale
- Unicode conformant collation, normalization, and text boundary algorithms
- Simultaneous availability of multiple locales in the same application
- Code set independent locales such that all Unicode characters are usable in any locale

The following features are not provided for server-side locale support and must be provided by a client:

- Graphical user interface
- User input (for example, keyboard mapping, and input methods)
- Final output (for example, display, fonts, character shaping, and printing)

In globalization support, the source files containing locale definitions might be different and inconsistent because of different standards. Two major locale definitions are used to build locale objects: IBM and Unicode Common Locale Data Repository (CLDR) definitions.

Table 15. Unicode encoded languages and locales in AIX

Language	Territory or region	Code set	Default locale name	Aliases	Translated?	Client support provided?	Default LFT keyboard ID	CLDR locale?	Introduced in AIX release
Afrikaans	South Africa	UTF-8	af_ZA.UTF-8		No	No	103P	Yes	7.1.1.0

Globalization reference

This section provides information about the globalization checklist and multicultural support subroutines.

Globalization checklist

The globalization checklist provides a way to analyze a program for translation and multicultural support dependencies. By going through this list, one can determine what, if any, globalization functions must be

considered. This is useful for both programming and testing. If you identify a set of globalization items that a program depends on, a test strategy can be developed. This facilitates a common approach to testing all programs.

All major globalization considerations have been identified. However, this list is not all-encompassing. There may be other globalization questions that are not listed.

Program operation checklist

1. Does the program display translatable messages to the user, either directly or indirectly? An example of indirect messages are those that are stored in libraries.

If yes:

- Are these messages externalized from the program by way of the message facility subroutines?
- Have you provided message source files for all such messages?
- What is the locale under which the program runs?

- If it runs in the locale determined by the locale environment variables, did you invoke the **setlocale** subroutine in the following manner?

```
setlocale(LC_ALL, "")
```

Note: The locale categories, in their predefined hierarchical order, are: **LC_ALL**, **LC_COLLATE**, **LC_CTYPE**, **LC_MESSAGES**, **LC_MONETARY**, **LC_NUMERIC**, and **LC_TIME**.

- If the program runs in the "C" locale, except for displaying messages in the locale specified by the locale environment variables, did you invoke the **setlocale** subroutine in the following manner?

```
setlocale(LC_MESSAGES, "")
```

- After invoking the **setlocale** subroutine, did you invoke the **catopen** subroutine in the following manner?

```
catopen(catalog_name, NL_CAT_LOCALE)
```

- Did you invoke the **catopen** subroutine with the proper catalog name?
- See the "Message facility" on page 148 for more information about translatable messages.

2. Does the program compare text strings?

If yes:

- Are the strings compared to check equality only?

If yes:

- Use the **strcmp** or **strncmp** subroutine.
- Do not use the **strcoll** or **strxfrm** subroutine.

- Are the strings compared to see which one sorts before the other, as defined in the current locale?

If yes:

- Invoke the **setlocale** subroutine in the following manner:

```
setlocale(LC_ALL, "")
```

- Use the **strcoll**, **strxfrm**, **wscoll**, or **wcsxfrm** subroutine.
- Do not use the **strxfrm** or **strncmp** subroutine.

3. Does the program parse path names of files?

If yes:

- If looking for / (slash), use the **strchr** subroutine.
- If looking for characters, be aware that the file names can include multibyte characters. In such cases, invoke the **setlocale** subroutine in the following manner and then use appropriate search subroutines:

```
setlocale(LC_ALL, "")
```

4. Does the program use system names, such as node names, user names, printer names, and queue names?

If yes:

 - System names can have multibyte characters.
 - To identify a multibyte character, first invoke the **setlocale** subroutine in the following manner and then use appropriate subroutines in the library.

```
setlocale(LC_ALL, "")
```
5. Does the program use character class properties, such as uppercase, lowercase, and alphabetic?

If yes:

 - Invoke the **setlocale** subroutine in the following manner:

```
setlocale(LC_ALL, "")
```
 - Do not make assumptions about character properties. Always use system subroutines to determine character properties.
 - Are the characters restricted to single-byte code sets?

If yes:

 - Use one of the **ctype** subroutines: **isalnum**, **isalpha**, **isctrl**, **isdigit**, **isgraph**, **isprint**, **isspace**, or **isxdigit**.
 - If not, the characters may be multibyte characters:
 - Use the **iswalnum**, **iswalph**, **iswcntrl**, **iswdigit**, **iswgraph**, **iswlower**, **iswprint**, **iswpunct**, **iswspace**, **iswupper**, or **iswxdigit** subroutine.
6. Does the program convert the case (upper or lower) of characters?

If yes:

 - Invoke the **setlocale** subroutine in the following manner:

```
setlocale(LC_ALL, "")
```
 - Are the characters restricted to single-byte code sets?

If yes:

 - Use these **conv** subroutines: **_tolower**, **_toupper**, **tolower**, or **toupper**.
 - If not, the characters may be multibyte characters:
 - Use the **towlower** or **towupper** subroutine.
7. Does the program keep track of cursor movement on a tty terminal?

If yes:

 - Invoke the **setlocale** subroutine in the following manner:

```
setlocale(LC_ALL, "")
```
 - You may need to determine the display column width of characters. Use the **wcwidth** or **wcswidth** subroutine.
8. Does the program perform character I/O?

If yes:

 - Invoke the **setlocale** subroutine in the following manner:

```
setlocale(LC_ALL, "")
```
 - Are the characters restricted to single-byte code sets?

If yes:

 - Use following subroutine families:
 - **fgetc**, **getc**, **getchar**, **getw**
 - **fgets**, **gets**
 - **fputc**, **putc**, **putchar**, **putw**
 - **printf**, **scanf**

If not:

- Use following subroutine families:
 - **fgetwc, getwc, getwchar**
 - **fgetws, getws**
 - **fputwc, putwc, putwchar**

9. Does the program step through an array of characters?

If yes:

- Is the array limited to single-byte characters only?

If yes:

- Does not require **setlocale(LC_ALL, "")**
- If *p* is the pointer to this array of single-byte characters, step through this array using *p++*.

If not:

- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
- Use the **mblen** or **wcslen** subroutine.

10. Does the program need to know the maximum number of bytes used to encode a character within the code set?

If yes:

- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
- Use the **MB_CUR_MAX** macro.

11. Does the program format date or time numeric quantities?

If yes:

- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
- Use the **nl_langinfo** or **localeconv** subroutine to obtain the locale-specific information.
- Use the **strftime** or **strptime** subroutine.

12. Does the program format numeric quantities?

If yes:

- Invoke the
`setlocale`

subroutine in the following manner:

`setlocale(LC_ALL, "")`

- Use the **nl_langinfo** or **localeconv** subroutine to obtain the locale-specific information.
- Use the following pair of subroutines, as needed: **printf**, **scanf**.

13. Does the program format monetary quantities?

If yes:

- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
- Use the **nl_langinfo** or **localeconv** subroutine to obtain the locale-specific information.
- Use the **strfmon** subroutine to format monetary quantities.

14. Does the program search for strings or locate characters?

If yes:

- Are you looking for single-byte characters in single-byte text?
 - Does not require `setlocale(LC_ALL, "")`

- Use standard **libc** string subroutines such as the **strchr** subroutine.
 - Are you looking for characters in the range 0x00-0x3F (the unique code-point range)?
 - Does not require `setlocale(LC_ALL, "")`
 - Use standard **libc** string subroutines such as the **strchr**, **strcspn**, **strpbrk**, **strchr**, **strspn**, **strstr**, **strtok**, and **memchr** subroutines.
 - Are you looking for characters in the range 0x00-0xFF?
 - Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
 - Two methods are available:
Use the **mblen** subroutine to skip multibyte characters. Then, on encountering single-byte characters, check for equality. See checklist item 2.
OR
Convert the search character and the searched string to wide character form, and then use wide character search subroutines.
15. Does the program perform regular-expression pattern matching?
- If yes:
- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
 - Use the **regcomp**, **regex**, or **regerror** subroutine.
16. Does the program ask the user for affirmative/negative responses?
- If yes:
- Invoke the **setlocale** subroutine in the following manner:
`setlocale(LC_ALL, "")`
 - Put the prompt in the message catalog. Use the **catopen** and **catgets** subroutines to retrieve the catalog and display the prompt.
 - Use the **rpmatch** subroutine to match the user's response.
17. Does the program use special box-drawing characters?
- If yes:
- Do not use code set-specific box-drawing characters.
 - Instead use the box-drawing characters and attributes specified in the **terminfo** file.
18. Does the program perform culture-specific or locale-specific processing that is not addressed here?
- If yes:
- Externalize the culture-specific modules. Do not make them part of the executable program.
 - Load the modules at run time using subroutines provided by the system, such as the **load** subroutine.
 - If the system does not provide such facilities, link them statically but provide them in a modular fashion.

Related concepts:

“Setting the Locale” on page 13

Every globalized program must set the current locale using the **setlocale** subroutine. This subroutine allows a process to change or query the current locale by accessing locale databases.

“Message facility” on page 148

It is necessary to keep messages separate from the program by providing them in the form of message catalogs that the program can access at run time. This arrangement facilitates translations of messages into various languages and make them available to a program based on a user's locale. To aid in this task, commands and subroutines are provided by the Message Facility.

“Wide character classification subroutines” on page 27

The majority of wide character classification subroutines are similar to traditional character classification subroutines, except that wide character classification subroutines operate on a **wchar_t** data type argument passed as a **wint_t** data type argument.

AIXwindows checklist

The remaining checklist items are specific to the AIXwindows systems.

1. Does your program use the font set specification in order to be code-set independent in X applications?
2. Does your client use labels, buttons, or other output-only widgets to display translatable messages?
If yes:
 - Invoke the ***XtSetLanguageProc** subroutine in the following manner:
`XtSetLanguageProc(NULL, NULL, NULL);`
 - Messages can be placed in either message catalogs or localized resource files. See checklist items 1 or 20, respectively.
 - To make the widgets code set-independent, specify fonts that use font sets.
3. Does your client use X resource files to define the text of labels, buttons, or text widgets?
If yes:
 - Put all resources that need translation in one place.
 - Consider using message catalogs for the text strings.
 - Do not use translated color names, since color names are restricted to one encoding. The only portable names are encoded in the portable character set.
 - Put language-specific resource files in `/usr/lib/X11/%L/app-defaults/%N`, where `%L` is the name of the locale, such as `fr_FR`, and `%N` is the name of the client.
4. Is keyboard input localized by language?
If yes:

- Invoke the ***XtSetLanguageProc** subroutine in the following manner:
`XtSetLanguageProc(NULL, NULL, NULL);`
 - Use the **XmText** or **XmTextField** widgets for all text input.
 Some of the **XmText** widgets' arguments are defined in terms of character length instead of byte length. The cursor position is maintained in character position, not byte position.
 - Are you using the **XmDrawingArea** widget to do localized input?
 - Use the input method subroutines to do input processing in different languages.
5. Does your client present lists or labels consisting of localized text from user files rather than from X resource files?
- If yes:
- Invoke the ***XtSetLanguageProc** subroutine in the following manner:
`XtSetLanguageProc(NULL, NULL, NULL);`
 - Use the **XmStringCreateSimple** subroutine to create the **XmString** data type for localized text. The **XmStringCreate** subroutine can be used, but **XmSTRING_DEFAULT_CHARSET** is preferable.
 - To make the widgets code-set independent, specify fonts by using font sets. Font resources (for example, ***fontList:** instead) in the app-defaults files should use the upper case and class form rather than the lower case form (for example, ***FontList:** instead). This allow the desktop style manager to affect the application font selection.
6. Does your program do any presentation operations (Xlib drawing, printing, formatting, or editing) on bidirectional text?
- If yes:
- Use the **XmText** or **XmTextField** in the Xm (Motif) library. These widgets are enabled for bidirectional text.
 - If the Xm library can not be used, use the layout subroutines to perform any re-ordering and shaping on the text.
 - Store and communicate the text in the implicit (logical) form. Some utilities (for example, **aixterm**) support the visual form of bidirectional text, but most multicultural support subroutines cannot process the visual form of bidirectional text.

If the response to all of the above items is no, the program probably has no multicultural support dependencies. In this case, you might not need the locale-setting subroutine **setlocale** and the catalog facility subroutines **catopen** and **catgets**.

Related concepts:

“Message facility” on page 148

It is necessary to keep messages separate from the program by providing them in the form of message catalogs that the program can access at run time. This arrangement facilitates translations of messages into various languages and make them available to a program based on a user's locale. To aid in this task, commands and subroutines are provided by the Message Facility.

“Input methods” on page 119

For an application to run in the international environment for which globalization provides a base, input methods are needed. The Input Method is an application programming interface (API) that allows you to develop applications independent of a particular language, keyboard, or code set.

List of multicultural support subroutines

The multicultural support subroutines are used for handling locale-specific information, manipulating wide characters and multibyte characters, and using regular expressions.

Related concepts:

“List of locale subroutines”

The section will list the subroutines provided to obtain and process locale-specific data.

“Subroutines for multicultural support” on page 13

This section guides programmers in using subroutines when developing portable globalized programs. Use standard Open Group, ISO/ANSI C, and POSIX functions to maximize portability.

List of locale subroutines

The section will list the subroutines provided to obtain and process locale-specific data.

The following subroutines are provided to obtain and process locale-specific data:

Subroutine	Description
localeconv	Retrieves locale-dependent conventions of a program locale.
nl_langinfo	Returns information on language or cultural area in a program locale.
rpmatch	Determines whether a response is affirmative or negative in the current locale.
setlocale	Changes or queries a program's current locale.

Related concepts:

“List of multicultural support subroutines”

The multicultural support subroutines are used for handling locale-specific information, manipulating wide characters and multibyte characters, and using regular expressions.

List of time and monetary formatting subroutines

Subroutine	Description
strfmon	Formats monetary strings according to the current locale.
strftime	Formats time and date according to the current locale.
strptime	Converts a character string to a time value according to the current locale.
wcsftime	Converts time and date into a wide character string according to the current locale.

List of multibyte character subroutines

Subroutine	Description
mblen	Determines the length of a multibyte character.
mbstowcs	Converts a multibyte character string to a wide character string.
mbtowc	Converts a multibyte character to a wide character.

List of wide character subroutines

The following subroutines process characters in process-code form:

Subroutine	Description
fgetwc	Gets a wide character or word from an input stream.
fgetws	Gets a wide character string from a stream.
fputwc	Writes a wide character or a word to a stream.
fputws	Writes a wide character string to a stream.
getwc	Gets a wide character or word from an input stream.
getwchar	Gets a wide character or word from an input stream.
getws	Gets a wide character string from a stream.
iswalnum	Determines if the wide character is alphanumeric.
iswalpha	Determines if the wide character is alphabetic.
iswcntrl	Determines if the wide character is a control character.
iswctype	Determines the property of a wide character.
iswdigit	Determines if the wide character is a digit.
iswgraph	Determines if the wide character (excluding "space characters") is a printing character.
iswlower	Determines if the wide character is lowercase.
iswprint	Determines if the wide character (including "space characters") is a printing character.
iswpunct	Determines if the wide character is a punctuation character.
iswspace	Determines if the wide character is a blank space.
iswupper	Determines if the wide character is uppercase.
iswxdigit	Determines if the wide character is a hexadecimal digit.
putwc	Writes a wide character or a word to a stream.
putwchar	Writes a wide character or a word to a stream.
putws	Writes a wide character string to a stream.

Subroutine	Description
<code>strcoll</code>	Compares two strings based on their collation weights in the current locale.
<code>strxfrm</code>	Transforms a string into locale collation values.
<code>towlower</code>	Converts an uppercase wide character to a lowercase wide character.
<code>towupper</code>	Converts a lowercase wide character to an uppercase wide character.
<code>ungetwc</code>	Pushes a wide character onto a stream.
<code>wcsid</code>	Returns the charsetID of a wide character.
<code>wscat</code>	Concatenates wide character strings.
<code>wcschr</code>	Searches for a wide character.
<code>wcscmp</code>	Compares wide character strings.
<code>wscoll</code>	Compares the collation weights of wide character strings.
<code>wscpy</code>	Copies a wide character string.
<code>wcscspn</code>	Searches for a wide character string.
<code>wcslen</code>	Determines the number of characters in a wide character string.
<code>wcsncat</code>	Concatenates a specified number of wide characters.
<code>wcsncmp</code>	Compares a specified number of wide characters.
<code>wcsncpy</code>	Copies a specified number of wide characters.
<code>wcspbrk</code>	Locates the first occurrence of wide characters in a wide character string.
<code>wcsrchr</code>	Locates the last occurrence of wide characters in a wide character string.
<code>wcsspn</code>	Returns the number of wide characters in the initial segment of a string.
<code>wcstod</code>	Converts a wide character string to a double-precision floating point value.
<code>wcstok</code>	Breaks a wide character string into a sequence of separate wide character strings.
<code>wcstol</code>	Converts a wide character string to a long integer value.
<code>wcstombs</code>	Converts a sequence of wide characters to a sequence of multibyte characters.
<code>wcstoul</code>	Converts a wide character string to an unsigned, long integer value.
<code>wcswcs</code>	Locates the first occurrence of a wide character sequence in a wide character string.
<code>wcswidth</code>	Determines the display width of a wide character string.
<code>wcsxfrm</code>	Converts a wide character string to values representing character collation weights.
<code>wctomb</code>	Converts a wide character to a multibyte character.
<code>wctype</code>	Gets a handle for valid property names as defined in the current locale.
<code>wcwidth</code>	Determines the display width of a wide character.

List of layout library subroutines

The following subroutines of the layout library (**libi18n.a**) transform bidirectional and context-dependent text to different formats:

Subroutine	Description
<code>layout_object_create</code>	Initializes a layout context.
<code>layout_object_free</code>	Frees a LayoutObject structure.
<code>layout_object_editshape</code>	Edits the shape of the context text.
<code>layout_object_getvalue</code>	Queries the current layout values of a LayoutObject structure.
<code>layout_object_setvalue</code>	Sets the layout values of a LayoutObject structure.
<code>layout_object_shapeboxchars</code>	Shapes box characters.
<code>layout_object_transform</code>	Transforms the text according to the current layout values of a LayoutObject structure.

List of message facility subroutines

The message facility consists of standard defined subroutines and commands, and manufacturer value-added extensions to support externalized message catalogs. These catalogs are used by an application to retrieve and display messages, as needed. The following message facility subroutines get messages for an application:

Subroutine	Description
<code>catopen</code>	Opens a catalog.
<code>catgets</code>	Gets a messages from a catalog.
<code>catclose</code>	Closes a catalog.
<code>strerror</code>	Maps an error number to an error-message string appropriate for the current locale.

List of converter subroutines

In an internationalized environment, it is often necessary to convert data from one code set to another. The following converter subroutines are supported for this purpose:

Subroutines	Description
<code>iconv_open</code>	Performs the initialization required to convert characters from the code set specified by the FromCode parameter to the code set specified by the ToCode parameter.
<code>iconv</code>	Invokes the converter function using the descriptor obtained from the <code>iconv_open</code> subroutine.
<code>iconv_close</code>	Closes the conversion descriptor specified by the <code>cd</code> variable and makes it usable again.
<code>ccsidtocs</code>	Returns the code-set.

List of input method subroutines

The Input Method is a set of subroutines that translate key strokes into character strings in the code set specified by a locale. The Input Method subroutines include logic for locale-specific input processing and keyboard controls (for example, Ctrl, Alt, Shift, Lock, and Alt-Graphic). The following subroutines support this Input Method:

Subroutines	Description
IMAIXMapping	Translates a pair of <i>KeySymbol</i> and <i>State</i> parameters to a string and returns a pointer to that string.
IMAuxCreate	Tells the application program to create an auxiliary area.
IMAuxDestroy	Notifies the callback to destroy any knowledge of the auxiliary area.
IMAuxDraw	Tells the application program to draw the auxiliary area.
IMAuxHide	Tells the application program to hide the auxiliary area.
IMBeep	Tells the application program to emit a beep sound.
IMClose	Closes the input method.
IMCreate	Creates one instance of a particular input method.
IMDestroy	Destroys an input method instance.
IMFilter	Checks whether a keyboard event is used by the input method for its internal processing.
IMFreeKeymap	Frees resources allocated by the IMInitializeKeymap subroutine.
IMIndicatorDraw	Tells the application program to draw the indicator.
IMIndicatorHide	Tells the application program to hide the indicator.
IMInitialize	Initializes the input method for a particular language.
IMInitializeKeymap	Initializes the input method for a particular language.
IMIoctl	Performs a variety of control or query operations on the input method.
IMLookupString	Maps a keyboard-symbol/state pair to a string defined by the user.
IMProcessAuxiliary	Notifies the input method of input for an auxiliary area.
IMQueryLanguage	Checks to see if the specified language is supported.
IMSimpleMapping	Translates a pair of <i>KeySymbol</i> and <i>State</i> parameters to a string a returns a pointer to that string.
IMTextCursor	Sets the new display cursor position.
IMTextDraw	Asks the application program to draw the next string.
IMTextHide	Tells the application program to hide the text area.
IMTextStart	Notifies the application program of the length of the pre-editing space.

List of regular expression subroutines

The following subroutines handle regular expressions:

Subroutine	Description
regcomp	Compiles a regular expression for comparison by the regex subroutine.
regerror	Returns the error message, appropriate for the current locale, that corresponds to the error code returned by either the regcomp or regex subroutine.
regex	Compares a string with a compiled regular expression from a previous call to the regcomp subroutine.
regfree	Frees any memory allocated by a previous call to the regcomp subroutine.

Related concepts:

“Subroutines for multicultural support” on page 13

This section guides programmers in using subroutines when developing portable globalized programs. Use standard Open Group, ISO/ANSI C, and POSIX functions to maximize portability.

Character maps

This section contains textual representations of character maps.

This section has the textual representations of the character maps discussed in “Code sets for multicultural support” on page 47.

ISO code sets

This section describes the ISO code sets.

Multicultural support sample program

This section contains a sample program fragment, `my_example.c`, which illustrates globalization through code set independent programming.

Related concepts:

“Code set independence” on page 11

The system needs certain information about code sets to communicate with the external environment. This information is hidden by the code set-independent library subroutines (globalization library). These subroutines pass information to the code set-dependent functions. Because multicultural support subroutines handle the necessary code set information, you do not need explicit knowledge of any code set when you write programs that process characters. This programming technique is called *code set independence*.

Message source file for `my_example`

A sample message source file for the `my_example` utility is given here. Note that we defined only one set and three messages in this catalog for illustration purposes only. A typical catalog contains several such messages.

The following is the message source file for `my_example`, `my_example.msg`.

```
$quote "  
$set MS_MY_EXAMPLE  
CANTOPEN      "my_example: cannot open %s\n"  
BYTECNT       "number of bytes: %d\n"  
CHARCNT       "number of characters: %d"
```

Creation of message header file for `my_example`

To generate the run-time catalog, use the `runcat` command as follows:

```
runcat my_example my_example.msg
```

This generates the `my_example_msg.h` header file, as shown in the following section. Note that the set mnemonic is `MS_MY_EXAMPLE` and the message mnemonics are `CANTOPEN`, `BYTECNT`, and `CHARCNT`. These mnemonics are used in the programs in this appendix.

```
/*  
** The header file: my_example_msg.h is as follows:  
*/  
  
#ifndef _H_MY_EXAMPLE_MSG  
#define _H_MY_EXAMPLE_MSG  
#include <limits.h>  
#include <nl_types.h>  
#define MF_MY_EXAMPLE "my_example.cat"  
  
/* The following was generated from my_example.msg. */  
  
/* definitions for set MS_MY_EXAMPLE */  
#define MS_MY_EXAMPLE 1  
  
#define CANTOPEN 1  
#define BYTECNT 2  
#define CHARCNT 3  
  
#endif
```

Single-source, single-path code set independent version

The term *single-source single-path* refers to one path in a single application to be used to process both single-byte and multibyte code sets. The single source single path method eliminates all `ifdefs` for globalization. All characters are handled the same way, whether they are members of single-byte or multibyte code sets.

Single-source single-path is desirable, but it can degrade performance. Thus, it is not recommended for all programs. There may be some programs that do not suffer any performance degradation when they are fully globalized; in those cases, use the single-source single-path method.

The following fully globalized version of the `my_example` utility supports all code sets through single source single path, code set independent programming:

```
/*
 * COMPONENT_NAME:
 *
 * FUNCTIONS: my_example
 *
 * The following code shows how to count the number of bytes and
 * the number of characters in a text file.
 *
 * This example is for illustration purposes only. Performance
 * improvements may still be possible.
 */

#include <stdio.h>
#include <ctype.h>
#include <locale.h>
#include <stdlib.h>
#include "my_example_msg.h"

#define MSGSTR(Num,Str) catgets(catd,MS_MY_EXAMPLE,Num,Str)

/*
 * NAME: my_example
 *
 * FUNCTION: Counts the number of characters in a file.
 */

main(argc,argv)
int argc;
char **argv;
{
    int    bytesread, /* number of bytes read */
          bytesprocessed;
    int    leftover;

    int    i;
    int    mbcnt;      /* number of bytes in a character */
    int    f;         /* File descriptor */
    int    mb_cur_max;
    int    bytect;     /* name changed from charct... */
    int    charct;     /* for real character count */
    char   *curp, *cure; /* current and end pointers into
                          ** buffer */
    char   buf[BUFSIZ+1];

    nl_catd    catd;

    wchar_t   wc;

    /* Obtain the current locale */
    (void) setlocale(LC_ALL,"");
}
```

```

/* after setting the locale, open the message catalog */
catd = catopen(MF_MY_EXAMPLE,NL_CAT_LOCALE);

/* Parse the arguments if any */

/*
** Obtain the maximum number of bytes in a character in the
** current locale.
*/
mb_cur_max = MB_CUR_MAX;
i = 1;

/* Open the specified file and issue error messages if any */
f = open(argv[i],0);
if(f<0){
    fprintf(stderr,MSGSTR(CANTOPEN,          /*MSG*/
        "my_example: cannot open %s\n"), argv[i]); /*MSG*/
    exit(2);
}

/* Initialize the variables for the count */
bytect = 0;
charct = 0;

/* Start count of bytes and characters */

leftover = 0;

for(;;) {
    bytesread = read(f,buf+leftover, BUFSIZ-leftover);
    /* issue any error messages here, if needed */
    if(bytesread <= 0)
        break;

    buf[leftover+bytesread] = '\0';
    /* Protect partial reads */
    bytect += bytesread;
    curp=buf;
    cure = buf + bytesread+leftover;
    leftover=0; /* No more leftover */

    for(; curp<cure ;){
        /* Convert to wide character */
        mbcnt= mbtowc(&wc, curp, mb_cur_max);
        if(mbcnt <= 0){
            mbcnt = 1;
        }else if (cure - curp >=mb_cur_max){
            wc = *curp;
            mbcnt =1;
        }else{
            /* Needs more data */
            leftover= cure - curp;
            strcpy(buf, curp, leftover);
            break;
        }
        curp +=mbcnt;
        charct++;
    }
}

/* print number of chars and bytes */
fprintf(stderr,MSGSTR(BYTECNT, "number of bytes:%d\n"),
    bytect);
fprintf(stderr,MSGSTR(CHARCNT, "number of characters:%d\n"),

```

```

        charct);
    close(f);
    exit(0);
}

```

Single-source, dual-path version optimized for single-byte code sets

The term *single-source dual-path* refers to two paths in a single application where one of the paths is chosen at run time depending on the current locale setting, which indicates whether the code set in use is single-byte or multibyte.

If a program can retain its performance and not increase its executable file size too much, the single-source dual-path method is the preferred choice. You should evaluate the increase in the executable file size on a per command or utility basis.

In the single-source dual-path method, the **MB_CUR_MAX** macro specifies the maximum number of bytes in a multibyte character in the current locale. This should be used to determine at run time whether the processing path to be chosen is the single-byte or the multibyte path. Use a boolean flag to indicate the path to be chosen, for example:

```

int mbcodeset ;
/* After setlocale(LC_ALL,"") is done, determine the path to
** be chosen.
*/
if(MB_CUR_MAX == 1)
    mbcodeset = 0;
else    mbcodeset = 1;

```

This way, the current code set is checked to see if it is a multibyte code set and if so, the flag `mbcodeset` is set appropriately. Testing this flag has less performance impact than testing the **MB_CUR_MAX** macro several times.

```

if(mbcodeset){
    /* Multibyte code sets (also supports single-byte
    ** code sets )
    */
    /* Use multibyte or wide character processing
    functions */
}else{
    /* single-byte code sets */
    /* Process accordingly */
}

```

The preceding approach is appropriate if globalization affects a small proportion of a module. Excessive tests for providing dual paths may degrade performance. Provide the test at a level that precludes frequent testing for this case.

The following version of the `my_example` utility produces one object, yet at run time, the appropriate path is chosen based on the code set to optimize performance for that code set. Note that we distinguish between single-byte and multibyte code sets only.

```

/*
 * COMPONENT_NAME:
 *
 * FUNCTIONS: my_example
 *
 * The following code shows how to count the number of bytes and
 * the number of characters in a text file.
 *
 * This example is for illustration purposes only. Performance
 * improvements may still be possible.
 *
 */

```

```

#include      <stdio.h>
#include      <ctype.h>
#include      <locale.h>
#include      <stdlib.h>
#include      "my_example_msg.h"

#define MSGSTR(Num,Str) catgets(catd,MS_MY_EXAMPLE,Num,Str)

/*
 * NAME: my_example
 *
 * FUNCTION: Counts the number of characters in a file.
 *
 */

main(argc,argv)
int argc;
char **argv;
{
    int bytesread, /* number of bytes read */
        bytesprocessed;
    int leftover;

    int i;
    int mbcnt; /* number of bytes in a character */
    int f; /* File descriptor */
    int mb_cur_max;
    int bytect; /* name changed from charct... */
    int charct; /* for real character count */
    char *curp, *cure; /* current and end pointers into buffer */
    char buf[BUFSIZ+1];

        nl_catd catd;

        wchar_t wc;

        /* flag to indicate if current code set is a
        ** multibyte code set
        */
        int multibytecodeset;

        /* Obtain the current locale */
        (void) setlocale(LC_ALL,"");

        /* after setting the locale, open the message catalog */
        catd = catopen(MF_MY_EXAMPLE,NL_CAT_LOCALE);

        /* Parse the arguments if any */

        /*
        ** Obtain the maximum number of bytes in a character in the
        ** current locale.
        */
        mb_cur_max = MB_CUR_MAX;

        if(mb_cur_max >1)
            multibytecodeset = 1;
        else
            multibytecodeset = 0;

        i = 1;

        /* Open the specified file and issue error messages if any */
        f = open(argv[i],0);
        if(f<0){
            fprintf(stderr,MSGSTR(CANTOPEN, /*MSG*/
                "my_example: cannot open %s\n"), argv[i]); /*MSG*/

```

```

        exit(2);
    }

    /* Initialize the variables for the count */
    bytect = 0;
    charct = 0;

    /* Start count of bytes and characters */

    leftover = 0;
    if(multibytecodeset){
        /* Full globalization */
        /* Handles supported multibyte code sets */
        for(;;) {
            bytesread = read(f,buf+leftover,
                BUFSIZ-leftover);
            /* issue any error messages here, if needed */
            if(bytesread <= 0)
                break;

            buf[leftover+bytesread] = '\0';
            /* Protect partial reads */
            bytect += bytesread;
            curp=buf;

            cure = buf + bytesread+leftover;
            leftover=0; /* No more leftover */

            for(; curp<cure ;){
                /* Convert to wide character */
                mbcnt= mbtowlc(&wc, curp, mb_cur_max);
                if(mbcnt <= 0){
                    mbcnt = 1;
                }else if (cure - curp >=mb_cur_max){
                    wc = *curp;
                    mbcnt =1;

                }else{
                    /* Needs more data */
                    leftover= cure - curp;
                    strcpy(buf, curp, leftover);
                    break;
                }
                curp +=mbcnt;
                charct++;
            }
        }
    }else {

        /* Code specific to single-byte code sets that
        ** avoids conversion to widechars and thus optimizes
        ** performance for single-byte code sets.
        */

        for(;;) {
            bytesread = read(f,buf, BUFSIZ);
            /* issue any error messages here, if needed */
            if(bytesread <= 0)
                break;

            bytect += bytesread;
            charct += bytesread;
        }
    }
}

```

```

    /* print number of chars and bytes */
    fprintf(stderr,MSGSTR(BYTECNT, "number of bytes:%d\n"),
            bytect);
    fprintf(stderr,MSGSTR(CHARCNT, "number of characters:%d\n"),
            charct);
    close(f);
    exit(0);
}

```

Use of the libcur package

This section will discuss the changes that need to be made for programs that use the libcur package (extension to AT&T's libcurses package).

Programs that use the libcur package (extension to AT&T's libcurses package) need to make the following changes:

1. Remove the assumption that the number of bytes need to represent a character in a code set also represents the display column width of the character. Use the **wcwidth** subroutine to determine the number of display columns needed by the wide character code of a character.
2. **NLSCHAR** is redefined to be **wchar_t**.
3. The `win->y [y][x]` has **wchar_t** encodings.
4. Programs should not assume any particular encodings on the **wchar_t**.
5. Programs should use the **addstr**, **waddstr**, **mvaddstr**, and **mvwaddstr** subroutines rather than the **addch** family of subroutines. All string arguments are in multibyte form.
6. The **addch** and **waddch** subroutines accept a **wchar_t** encoding of the character. Programs that use these subroutines should ensure that **wchar_t** are used in calling these functions. The (x,y) are incremented by the number of columns occupied by the **wchar_t** passed to these subroutines.
7. The **delch**, **wdelch**, **mvdelch**, and **mvwdelch** subroutines support delete and backspace on multibyte characters depending on the current position of (x,y) . If the current (x,y) column position points to either the first or second column of a two-column character, the **delch** subroutine deletes both columns and shifts the rest of the line by the number of columns deleted.
8. The **insch**, **winsch**, **mvinsch**, and **mvwinsch** subroutines can be used to insert a **wchar_t** encoding of a character at the current (x,y) position. The line is shifted by the number of columns needed by the **wchar_t**.
9. The libcur package is modified to support box drawing characters as defined in the **terminfo** database and not assume the graphic characters in the IBM-850 code set. The libcur package supports drawing of primary and alternate box characters as defined in the **box_chars_1** and **box_chars_2** entries in the terminfo database. To use this, programs should be modified in the following fashion:

Drawing Primary box characters:

```

wcolorout(win, Bxa);
cbox(win);
wcolorend(win);

or,
wcolorout(win, Bxa);
drawbox(win, y,x, height, width);
wcolorend(win);

```

Drawing Alternate box characters:

```

wcolorout(win, Bya)
cboxalt(win);

```

```
wcolorend(win);

or,

wcolorout(win, Bxa);
drawbox(win, y, x, height, width);
wcolorend(win);
```

Bxa and Bya refer to the primary and alternate attributes defined in the **terminfo** database.

The following macros are added in the **cur01.h** file:

```
cboxalt(win)
```

```
drawboxalt(win, y,x, height, width)
```

10. Programs that need to support input of multibyte characters should not set **_extended** to TRUE by a call to **extended(TRUE)**. When the **_extended** flag is true, the **wgetch** subroutine returns **wchar_t** encodings of the character. With multibyte characters, this encoding of **wchar_t** may conflict with predefined values for escape sequences or function keys. Avoid this conflict when using multibyte code sets by setting **extended** to off (**extended(FALSE)**) before input. (The default is TRUE.)

Programs that do multibyte character input should do the following:

Input routine:

Example:

```
int c, count;
char buf[];

extended(FALSE); /* obtain one byte at a time */
count =0;
while(1){
    c = wgetch(); /* get one byte at a time */
    buf[count++] = c;
    if(count <=MB_CUR_MAX)
        if(mblen(buf, count) != -1)
            break; /* character found */
    else
        /*Error. No character can be found */
        /* Handle this case appropriately */
        break;
}
/* buf contains the input multibyte sequence */
/* Now handle PF keys, or any escape sequence here */
```

11. The **inch**, **winch**, **mvinch**, and **mvwinch** subroutines return the **wchar_t** at the current (x,y) position. Note that in the case of a double column width character, if the (x,y) point is at the first column, the **wchar_t** code of the double column width character is returned. If the (x,y) point is at the second column, WEOF is returned.
